Motor Symptoms and Signs While the patients usually complained of weakness of one leg it often seemed to the examiner that the weakness was more seeming than real due to protective spasm. Yet flaccid weakness and rarely paralysis were definitely observed in six patients, a unilateral foot-drop being a rare but striking finding. In the histories it is frequently noted that on some movement a stabbing pain in the back, perhaps radiating down one leg would be accompanied by an equally sudden transitory loss of power in that limb. **Atrophy**, always of slight degree, was associated with the weakness, and as expected was most conspicuous in gluteal, hamstring and calf muscles. As evidence of the slow progress of the disease in one patient it took seven years for the thigh and calf muscles to lose each four cm in circumference

Tremors, gross or fibrillary, were not observed

Reflexes The sole reflex abnormality noted in most cases was a loss of the Achilles jerk on the affected side, or of both in case of bilateral involvement. The associated plantar reflex was often not obtained, but was never extensor in type. Occasionally the knee jerk on the affected side was sluggish. The gluteal reflex was found diminished when this muscle was atrophied

Of greatest significance is the fact that in eight patients *no abnormality of the reflexes whatsoever could be demonstrated*

Sphincters Urinary and rectal incontinence were late manifestations in four cases always associated with bilateral involvement of the extremities.

In summarizing the clinical aspects of these twenty three cases, several points stand out and should be stressed

- 1 Pain is the first and with a few exceptions, remains the most important symptom throughout the course of illness. The pain is primarily in the low back with sciatic radiation mainly, and is increased by coughing, sneezing and bending

2. The symptoms and signs remain unilateral in more than half of the cases eight were on the left, and seven on the right side at the time of operation. Less frequently symptoms are bilateral from the onset or become bilateral during the course of the illness

3. No regular course of illness is indicated. In some cases the symptoms have progressed during two or three months with almost no interruption, with involvement of one lower extremity,

then the other, and finally sphincter loss. More frequently, however, symptoms have remained unilateral and have been intermittent over a period of many months or years, the patient enjoying relatively good health between attacks

Spinal Fluid Fluids were studied in twenty two of the twenty three cases. The significant fluid examinations in these cases have proved to be two only, an estimation of the protein content and the determination by manometry of subarachnoid block. The remainder of the examinations, cell count colloidal gold and Wassermann tests, have been routinely performed and found negative and of no diagnostic significance except to exclude syphilis and inflammatory disease

The technique of puncture has varied, at times a single needle below the lesion, on several occasions one needle above and one below but all too frequently because of the low site of the lesion we had to be satisfied with fluid obtained solely from above the site of the ruptured disc. Subarachnoid block nevertheless was determined by single or multiple puncture in eight cases. In no case was the block complete and often the latent period accompanying rise and fall in pressure in the manometer was indeed slight. In only three cases was the fluid from below the lesion xanthochromic

Whether obtained from above or below the lesion *every fluid showed an elevation of its protein contents*. For the most part the protein of the fluid was not excessive, even when from below the lesion although 1800 mg and 798 mg per 100 cc were obtained in two cases, the figures were usually less than 200 mg. From above the lesion the amounts were between 56 mg. and 91 mg per 100 cc (40 mg high normal by the technique used)

X Ray Examination Films, even stereoscopic, failed to show direct evidence of a ruptured disc. Rarely was a lesion hinted at by a slight narrowing of the disc (five cases), or by localized spur formation or arthritis. In one case only was arthritis marked and it was partly on the supposition that arthritis might explain the symptoms that operation was withheld for seven years.

Our experience with x ray examination following injection of lipiodol places this procedure as of prime importance in diagnosis and localization of disc rupture. In our earlier use of lipiodol, the lesion was not clearly disclosed, with our present technique, elaborated particularly by Dr. A. O. Hampton of the x ray department, we were frequently able to obtain results which were almost pathognomonic for herniation of the disc.

The technique is simple enough if two things are constantly kept in mind, i.e. that we are

trying to show a small mass which seldom causes compression of the whole cauda equina, and that the lesion always lies anterior to the dura. It is not our aim to show subarachnoid block, but to show a defect in the lipiodol shadow at the site of a protruded intervertebral disc. For this purpose the usual 15 cc or 2 cc of lipiodol, sufficient to demonstrate block, is not enough, and we now use 5 cc in order nearly to fill the lumbosacral canal. The injection is best made by puncture a little above the suspected lesion to prevent a breaking up of the oil into globules.

The patient in the *prone* position is then examined fluoroscopically on the tip table, films being taken when an excavation in the lipiodol shadow at the level of a disc becomes apparent. If the hernia is of the L 4-5 disc (as usual in this series), 5 cc of oil fills the canal above this point. Films taken with the patient sitting or standing and from various angles with the axis of the spine, usually localize the lesion (Figs 2, 3, 4 and 5).

Of the twenty-one patients of this group in whom lipiodol was employed, visualization of the hernia was satisfactory in sixteen. In the last ten cases of the series the demonstration has been so certain that a preoperative diagnosis of hernia of the disc has been made. In five patients who complained solely of unilateral pain and who showed no objective sensory, motor or reflex abnormality, an increased protein was found in the spinal fluid, and a characteristic notching of the lipiodol shadow correctly indicated a disc hernia.

Differential Diagnosis The majority of the cases of this series so closely resembled back strain, lumbosacral or sacro-iliac strain as to be indistinguishable from these conditions. When the symptoms were strictly unilateral, as they were in fifteen of the twenty-three cases, this diagnosis appeared quite satisfactory, indeed a very considerable number had been carried on as "sacro-iliac strain" for some time and would have been continued under this label if it had not been for the spinal fluid and lipiodol findings. Even the loss of an Achilles jerk, by far the commonest sign of nerve root involvement, was not considered conclusive, as it is maintained by some that this reflex may be lost in sacro-iliac affections.

It is unnecessary to recount numerous friendly discussions with our orthopedic confreres over these debatable cases, but the essence of the consultations briefly would come to this, that all would agree that the clinical picture presented was characteristic of sacro-iliac strain, or other orthopedic condition, and that we should operate for a herniated disc only if shown by lipiodol.

In the differential diagnosis, tumor also was considered. In no case did the clinical picture or x-ray findings suggest malignant disease of

the spine, and in no case was this diagnosis thought likely, yet benign neurofibroma or other intradural tumor would not have been a surprising finding in our earlier cases. We now feel that x-ray technique with lipiodol should usually differentiate these tumors from disc hernias, and in the last ten cases a preoperative diagnosis of ruptured disc has been found correct.

In two cases localized proliferation suggested old trauma and the intermittency of symptoms over a long period (in one case seven years) seemed consistent with root pressure of spinal origin, perhaps associated with intraspinal adhesions. In fact, the operation in one of these cases disclosed not only the disc hernia but a matting together of the cauda equina justifying our suspicions, in this case alone was evidence found suggestive of intraspinal trauma.

While a symptomatic diagnosis of sciatica was frequently made, in no case was the condition considered as sciatic neuritis.

RUPTURE OF DISC INTO CERVICAL CANAL

Age and sex incidence are similar to the previous group, the youngest being twenty-eight years, the eldest fifty-four years, all the patients except one were men. In one case only was there a causal history of trauma.

With one exception all the cases involved discs between the third and sixth cervical vertebrae, and with one exception the rupture was found primarily in the mid-line. As characteristic of this group Case 2 is presented in some detail.

CASE 2 M A P, No 327775 M G H, an unemployed mill worker of forty-four years, a native of Madeira, entered the hospital March 10, 1933 because of increasing difficulty in walking of two and one-half months, which had progressed so that at the time of admission he was unable to walk alone. For two weeks prior to this complaint he had noticed a numb sensation in both feet which had spread upward to his shoulders, associated with paroxysmal pain between the shoulder blades, increased by coughing. With the onset of the difficulty in walking the pain subsided, but the numbness persisted, mostly on the right side. He had noticed a transitory difficulty in starting the urine.

He presented a spastic quadriplegia especially marked on the right with lively reflexes throughout, bilateral ankle clonus and Babinski signs. While there was coarse tremor of the right arm, no atrophy was apparent. There appeared to be general hypalgesia on both sides of the body, but only on the left side was temperature sense disturbed. No sensory level or zone of hyperesthesia was made out.

Combined cisternal lumbar puncture showed a definite but not complete subarachnoid block, with cistern protein 20 mg and lumbar protein 138 mg per 100 cc.

X-rays disclosed proliferative changes about the margins of the bodies of the lower cervical vertebrae consistent with hypertrophic arthritis. No other variations from the normal were noted. Lipiodol injected into the cisterna magna (ex-

RUPTURE OF DISC INTO CERVICAL CANAL

Age and sex incidence are similar to the previous group, the youngest being twenty-eight years, the eldest fifty-four years, all the patients except one were men. In one case only was there a causal history of trauma.

With one exception all the cases involved discs between the third and sixth cervical vertebrae, and with one exception the rupture was found primarily in the mid-line. As characteristic of this group Case 2 is presented in some detail.

CASE 2 M A P, No 327775 M G H, an unemployed mill worker of forty four years, a native of Madeira, entered the hospital March 10, 1933 because of increasing difficulty in walking of two and one-half months, which had progressed so that at the time of admission he was unable to walk alone. For two weeks prior to this complaint he had noticed a numb sensation in both feet which had spread upward to his shoulders, associated with paroxysmal pain between the shoulder blades, increased by coughing. With the onset of the difficulty in walking the pain subsided, but the numbness persisted, mostly on the right side. He had noticed a transitory difficulty in starting the urine.

He presented a spastic quadriplegia especially marked on the right with lively reflexes throughout, bilateral ankle clonus and Babinski signs. While there was coarse tremor of the right arm, no atrophy was apparent. There appeared to be general hypalgesia on both sides of the body, but only on the left side was temperature sense disturbed. No sensory level or zone of hyperesthesia was made out.

Combined cisternal lumbar puncture showed a definite but not complete subarachnoid block, with cistern protein 20 mg and lumbar protein 138 mg per 100 cc.

X-rays disclosed proliferative changes about the margins of the bodies of the lower cervical vertebrae consistent with hypertrophic arthritides. No other variations from the normal were noted. Lipiodol injected into the cisterna magna (ex-

amination on the tip (ahlo) was temporarily arrested opposite the lower margin of the fifth cervical vertebra. The point of obstruction corresponded to the intervertebral disc.

At operation a disc tumor was in large part removed by means of an incision in the dura anteriorly. It was found by Dr C. S. Kuhl to be very firm tissue measuring $1.5 \times 0.5 \times 0.5$ cm., having the appearance of cartilage. The surface on all sides had a torn ragged appearance. Microscopically it consisted of fibrocartilage with a rather loose structure. There were only a few cartilage cells, these were evenly distributed through the fibrous matrix. The histological appearance corresponded very closely to that of nucleus pulposus.

Symptoms and Signs As would be expected, the clinical picture presented by the seven cases with mid line hernias was similar in many respects. Sometimes the earliest, and always the most important symptom to the patient, was motor disability of the lower extremities, bilateral stiffness, often with twitching of the legs and a sense of weakness, were the usual presenting symptoms. So insidious at times was the onset that in one man walking was noticed by his friends to be "peculiar" before he himself had observed anything wrong. At about the same time, or shortly before the appearance of stiffness of the legs, most patients experienced pain in the neck, frequently radiating to one or both shoulders, rarely down the spine, and made worse by coughing and sudden movements of the head. Numbness along the inner aspect of the arms and fingers was also commonly observed.

Increase in symptoms and signs usually is gradual, but there are seldom the long remissions noted in the lumbosacral group. Difficulty in walking generally demands attention in from two to four months, but in one case the progress of the disease was so slow that four years had elapsed before the gait was noticeably abnormal. A sense of numbness of the body, and occasionally difficulty in starting the urinary stream added to the discomfort of the patients.

For the most part these symptoms were bilaterally symmetrical from their onset, but in at least two cases a distinct inequality on the two sides was present.

The motor examination as expected showed typically spastic paraplegia without ataxia, with bilateral Babinski signs and ankle clonus. The upper extremities were normal or with alteration of reflexes only, sometimes increased, sometimes decreased, but never with gross disability or atrophy. The sensory findings were as a rule minimal and uncertain although a zone of hyperalgesia could usually be found at the level of the second ribs, even when no certain anesthesia was indicated below. In one case only was there a Brown Séquard syndrome.

We have grouped the above seven cases together because of similar symptomatology and

signs produced by disc hernias primary in the mid line. The eighth case of this cervical spine series, in whom the hernia protruded from O 4-5 disc well to the left side, produced such a different clinical picture that it will be considered separately.

CASE 3 A. J. S., No 234269 M. G. H., a woman forty four years old was admitted to the hospital December 29 1933 because of pain weakness and wasting of the left arm. Eighteen months before while cranking up the body of a dump truck, he slipped and the crank hit his left arm just below the insertion of the deltoid muscle. Work was possible after a few days of pain at the site of the injury. A year after the accident he noticed numbness in the left arm and back and his arm from then on showed progressive weakness and wasting. Examination showed weakness and atrophy of the left deltoid in particular but a little weakness and atrophy of the biceps and triceps also although triceps and biceps reflexes were retained. There was an ill-defined hypesthesia to touch, pain and temperature sense in the upper arm. There was slight inequality of the pupils the right being greater than the left.

No abnormalities of the lower extremities could be made out. The spinal fluid showed no block, protein in the lumbar sac being 31 mg. X rays of the spine and left shoulder were negative. The condition was thought to be a traumatic brachial plexus injury.

The patient was readmitted to the hospital three months later because of increasing pain and weakness of the left arm. He now showed an increase since the previous examination in atrophy twitching of the deltoid muscle, hyperesthesia and tendon reflexes in this arm with a Hoffmann sign. The left knee-jerk was now livelier than the right, but without accompanying spasticity and with normal plantar response. Combined cistern lumbar puncture gave a questionable block with cistern protein 24 mg and lumbar protein 43 mg.

An intraspinal lesion seemed indicated and an exploratory laminectomy was done by Dr T. J. Patnam who found a mass, evidently arising from O 4-5 disc well out to the left side which compressed the spinal cord and over which the fifth cervical root passed. Unfortunately removal was found impossible without sacrificing the fifth root, so decompression alone was done.

Spinal Fluid Spinal fluid examinations of significance concern solely the dynamic tests for subarachnoid block and the protein content of the fluid. Block was demonstrated in seven of the eight cases, but was always partial, and sometimes very slight indeed even as judged by combined cisternal lumbar puncture which was used in five cases. In one case only block was not demonstrated. The protein content of the fluid below the block was slightly elevated as a rule, but in one case was actually below high normal. The protein figures varied from 32 mg to 186 mg per 100 cc. Xanthochromia was not observed.

X-Ray In no case did x ray examination show direct evidence of disc herniation. In one case a slight narrowing of the appropriate disc,

in two cases local spur formation and in two others scoliosis, suggested a lesion of some kind, but in none was the correct diagnosis possible from x-ray of the spine alone

Lipiodol injected into the cisterna magna was employed in six of the seven cases. There was definite lipiodol cap in four, and in one case in which no block had been demonstrated by fluid examination and no clinical level could be made out, it was the one dependable sign which led to operation. In one case, in which subarachnoid block was demonstrated by fluid examination, lipiodol passed down the canal without arrest, and in another case lipiodol seemed to be blocked at C 1, although the hernia was found at C 3-4.

In these cases the flow of lipiodol was followed fluoroscopically by examination of the patient on the tip table. The results are not uniformly satisfactory, yet in one case the evidence obtained was of paramount importance, and in three cases confirmatory evidence of block and localization was of such value as fully to justify the use of the oil.

DISCUSSION

Emphasis should be laid on the very considerable spasticity exhibited by these patients with little or no ataxia. This point has been stressed both by Elsberg⁹ and by Stookey¹⁰, and is amply corroborated by a study of our cases. Their explanation seems reasonable, namely, that the posterior columns are at too great a distance from the compressing hernia to be affected, certainly they are not so readily exposed as are the pyramidal tracts. We have sought for evidence of early loss of pain sense as found by Stookey¹⁰, but fail to show that there is regularly such dissociation.

We believe that the diagnosis of hernia of the intervertebral disc in the cervical region can be only tentative and that true neoplasm is always a possibility in these cases.

In several cases a diagnosis of multiple sclerosis was considered until the demonstration of block made that diagnosis untenable.

In the single case in which root pain and atrophy were present, a disc lesion was not seriously considered until early signs of compression became manifest, which justified an "exploratory" laminectomy. A herniated disc was unexpectedly found.

Three patients had herniations of the disc at the thoracic level. We shall not at this time discuss them except to say that a diagnosis of ruptured disc was not made before operation. The symptomatology differed from cervical spine hernia mainly in one respect, in all three cases ataxia was prominent.

OPERATIVE TREATMENT

The technique of operation on patients with unilateral symptoms indicating a disc lesion at

the lumbar level, differs considerably from the method usually employed in exploration of the cauda equina for tumor. The reason for this is that the position of the lesion makes its demonstration difficult in some instances. If the pre-operative signs and symptoms are clear-cut, we have fairly exact knowledge of the level and of the side involved. In such a case the laminectomy may be limited to two or three vertebrae, but it should extend well out on the side of the lesion. It is our practice to preserve the spinous processes, undercutting them and leaving them attached to the muscles of one side. Two laminae on the side involved are removed, carrying the exposure well out and removing the articular facets to give wider exposure. It is sometimes necessary to remove part of one pedicle. The lesion can usually be felt before the dura is opened, but it is frequently small and may be hidden far out in the intervertebral foramen.

Sometimes the nodule can be exposed by retracting the dura and reaching it from the side. At other times it is easier to open the dura and then incise it again over the lesion. The extruded portion of the disc may be opposite the disc from which it has been torn or may be just above or below it. The lesion feels smooth and hard, and is frequently hemispherical in shape. If lateral, it usually presses against the nerve roots lying in their sheath. The mass lies in front of a dense fibrous membrane, the posterior spinal ligament. When this is incised the disc fragment usually, lying free, can be picked up with forceps. Occasionally the fragment is firmly attached to the edge of the disc. Search will almost always reveal an opening running down into the nucleus pulposus (Fig 6).

Elsberg⁸ has described the technique of removal of these masses in the cervical and dorsal regions. We have followed his method closely. The dentate ligament is cut and the cord rotated, thus exposing the mass bulging through the anterior dura. Incision is made in the dura as he has described, and the fragment removed. It is our impression that the extruded fragment is more frequently connected with the disc than is the case in the lumbar region.

RESULTS

The first and perhaps the most striking result of operation in the lumbar cases is the immediate relief of pain in the leg. This relief has been complete and permanent in all but one of our cases. Some patients complain subsequently of lame back, but on the whole the operation has been most satisfactory. All of the patients have shown marked improvement in straight leg raising, many of them reaching eighty-five or ninety degrees of flexion. Tenderness of the lumbar spine is much less marked than before operation. Neurological signs, if present before operation, may or may not change.

Results in the patients with cervical lesions

have not been so satisfactory. Many continue to complain of the symptoms which they had before operation and remain spastic. On the whole, however, they too are improved.

In the whole series there has been one death attributable to the operation. In this case the wound was soiled with feces soon after operation, sepsis developed and the patient died of meningitis. Three others of the earlier group have since died, two probably as the result of urinary sepsis, while the cause of death in the third is unknown.

SUMMARY AND DISCUSSION

We realize that this subject opens up an interesting problem in industrial medicine. Injuries to the spine have long been a fruitful source of industrial accident compensation. It is unfortunate that we must further complicate this subject by adding another to the long list of possible injuries of the spine. We believe that this condition is rare as compared with back strain, fracture, sacro-iliac strain and the like, and that the diagnosis should not be made, even provisionally, without the proper evidence. We have stated that the examination of the spinal fluid and x-ray examination with lipiodal are of the greatest importance. We can say with equal emphasis that without increase of protein in the spinal fluid and without positive roentgenological evidence, even a tentative diagnosis of rupture of the intervertebral disc in the lumbar region should not be made. In the cervical region the differentiation of new growth and ruptured disc must at present remain obscure until proved at operation. This should go far toward preventing the loose application of this diagnosis to all defined injuries of the spinal column.

1. The Hernia

We believe that herniation of the intervertebral disc into the spinal canal is a definite pathological entity. The herniated mass producing symptoms and leading to operation has varied from $\frac{1}{2}$ to 2 cm. in size. Irrespective of the size, we wish to emphasize that neither from gross nor microscopic appearance do they resemble true cartilaginous or other tumors. It follows that increase in symptoms must be due in large part to progressive protrusion of the disc and modification of tissues adjacent rather than to added growth as in neoplasm.

The physiological mechanism causing the disc rupture is still undetermined and we do not wish to commit ourselves on this point. We have purposely avoided a title to the paper which stresses the nucleus pulposus as the cause of the rupture or which indicates that the mass found at operation is a chondroma. It may in time develop that the weak point allowing such a rupture will be found to be the result of disease of the annulus fibrosus. The occurrence

of these hernias chiefly in persons advanced in years perhaps favors a preëxisting degenerative process.

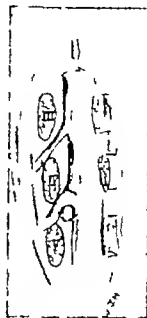

FIG. 7. Sketch from operation notes showing position of the lesion. C. S., M. G. H. No. 143385.

Trauma, as an immediate cause of rupture, appears to be quite certain in over one half of our lumbosacral group, and in this we are in agreement with Dandy, Alpers and others. In the cervicodorsal group, however, like Elsberg and Stoakey, we failed to obtain a definite history of injury.

We are unable to establish any type of individual patient or any occupation in which disc hernias predominate, but the excess of males over females so afflicted is worthy of comment, and in this respect we are in general agreement with other writers.

2. Symptomatology of the Lumbosacral Group

In general we have met with two groups of cases: those who present the clinical picture

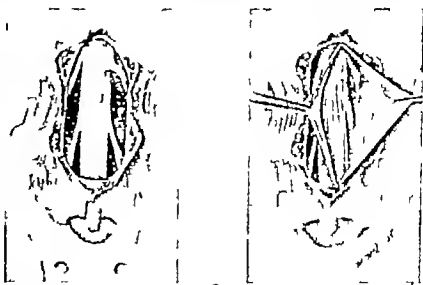

FIG. 8. Ruptured disc as seen at operation before and after opening the dura. J. M. C., M. G. H. No. 143381.

characteristic of sacro-iliac or low back strain, and those who present the picture of cauda equina tumor.

The first group is of the greatest interest in that these patients, suffering, intermittently

THE SYNDROME OF ANEMIA, GLOSSITIS, AND DYSPHAGIA*

Report of Cases

BY W B HOOVER, M D †

THE syndrome of anemia, glossitis and dysphagia has been recognized only of recent years. A brief review of the literature will be given, and the cases seen in the Lahey Clinic in the past four years will be reported with a few comments.

¹Plummer early noted the association of anemia and dysphagia in women. The latter was considered a hysterical manifestation. ²In 1919, A B Kelly described the syndrome under the title of "Spasm at the Entrance of the Oesophagus." Spasm was stressed because of the fact that on the passage of the esophagoscope, the folds of the narrowed esophagus gave way without undue pressure, and the treatment consisted of dilatation. ³Paterson described the condition at the same time in a paper entitled "A Clinical Type of Dysphagia." He particularly stressed the tongue devoid of papilla, changes in the mucosa and bands in various positions across the opening of the esophagus so that the opening was irregular, or an obliquely placed slit, and not always in the median line.

⁴In 1922, Porter P Vinson reported sixty-nine cases of "Hysterical Dysphagia." Since this report, the syndrome of anemia, glossitis, and dysphagia has frequently been referred to as the "Plummer Vinson Syndrome." Vinson noted splenomegaly in twelve of these sixty-nine cases. He did not find changes varying from the normal in the upper portion of the esophagus. His treatment consisted of dilatations, a liberal diet with iron and arsenic for anemia, and reassurance.

In 1926, Moersch and Conner also reported on sixty-five cases all in women. Glossitis was seen occasionally, the mucous membranes of the mouth were atrophic and dry, but webs or other membranous obstructions were not noted in the upper end of the esophagus. Splenomegaly was again recorded in twenty of the sixty-five cases. Achlorhydria was present in eight cases out of ten instances in which a gastric analysis was performed. Paresthesia of extremities was a feature in five cases. Their treatment was the same as that suggested by Vinson but they noted that in some cases the anemia preceded the dysphagia, an occurrence which was not in accord with Vinson's view that the anemia was due to an improper diet following dysphagia.

⁵A F Hurst in the same year reported a case in which it was impossible to pass the esophagoscope or mercury bougie, owing to "a tight spasm of the sphincter." This case had a

"streptococcal glossitis" and an anemia which preceded the dysphagia by two years. Improvement resulted following the administration of iron.

⁶Ryle reported another case in 1927, of esophageal spasm with severe anemia, and a recurrent ulceration of the tongue which the author thought to be a "streptococcal glossitis." The dysphagia was thought to be hysterical. The anemia responded to treatment with iron and arsenic, and the dysphagia was relieved by esophagoscopy.

⁷Jones and Owen also in 1928 reported on a series of cases. They recorded webs and membranes across the lumen of the esophagus, but also noted that the esophageal opening was lax without sphincter-like action occasionally. In 1929 ⁸Cameron reported twenty-five cases of this syndrome. Hydrochloric acid was present in the gastric content of all eleven cases in which an analysis was made. Dysphagia was preceded by anemia in five of his cases and the reverse was true in fifteen of his cases, and the remaining five a definite statement could not be made of the sequence of symptoms. Cameron stressed the possibility of malignant change at the upper end of the esophagus in women with this syndrome.

From 1929 to the present time there has been a great interest in anemia and numerous articles have appeared, under the titles of "Simple Achlorhydric Anemia" or similar titles (see titles listed below) by the following authors: ¹⁰Kaznelson, Reimann and Weiner, ¹¹Altshuller, ¹²Witts, ¹³Waugh, ¹⁴Mettler and Minot, ¹⁵McCann and Dye, ¹⁶Adamson and Smith, ¹⁷Davies, ¹⁸Mills, ²⁰Dameshek, ²¹Hare, ²²Hurst, ²³Haden, all describe a type of anemia with achlorhydria. Some of these observers have noted enlargement of the spleen, a sore mouth, atrophic tongue, and dysphagia to be occasionally present among their cases.

Returning to the reports of cases in which dysphagia and glossitis are important factors ²⁴Evans, in 1930, advanced the view that the underlying cause of this syndrome was tertiary syphilis of the third or fourth generation, but in view of a review of the literature, it would seem that his arguments are not well grounded.

Witts in 1931 gave a short review of the literature and reported the finding of this syndrome in thirteen instances. He pointed out the close correspondence between this syndrome and achlorhydric anemia. His conclusions were that the disease was not the result of streptococcus infection, that the anemia was not produced by dysphagia, and that the symptoms were not

*The Lahey Clinic Boston

†Hoover W B—Otorhinolaryngologist Lahey Clinic. For record and address of author see "This Week's Issue" page 432

the result of syphilis. His treatment consisted of a dilatation by the passage of bougies, and the anemia and glossitis usually improved following the administration of iron. He further noted that the administration of liver and dilute hydrochloric acid and the vitamin preparations did not seem to influence the anemia, glossitis or dysphagia.

Paterson confirmed his findings of 1919 and still held the view that the obstruction of the esophagus was due to spasm. He also stressed the frequency in which malignant growth developed in this syndrome. R. S. Johnson, in discussing Paterson's paper, pointed out that the dysphagia cleared up following bougies but that the change in hemoglobin concentration was very slow or did not take place at all unless liver extract and iron were given in large amounts. Achlorhydria was present in Johnson's cases.

Suzman in 1933 reports eight cases from the Massachusetts General Hospital. His paper is unique in that he is able to give the autopsy findings in one case. His comments on the findings in part are as follows: "From the gross findings, it is evident that a real obstruction brought about by raised folds of mucous membrane, was present.

"The mucosa and muscle of the tongue and esophagus showed definite histological abnormalities consisting chiefly of hyperkeratinization of the epithelium, with areas of desquamation and of degenerative, atrophic changes in the underlying muscle. Although there was a moderate degree of infiltration of the submucosa with lymphocytic like cells, on the whole, the condition did not appear to be inflammatory. The possibility that the hyperkeratinization of the epithelium may have been dependent on a deficiency of Vitamin A, is offset by the detection of significant amounts of this substance in the liver. The presence of areas of mucous membrane stimulating leukoplakia, and containing immature cells, exhibiting mitosis, is of interest in view of the tendency of malignant disease to develop."

One of Suzman's cases developed carcinoma in the pharynx and tongue but not of the upper end of the esophagus. This possibility of carcinomatous change has been emphasized by a number of observers. This is the only case of actual malignant change that I have found recorded in a patient with this syndrome. Suzman did not find changes in the intermuscular nerve plexus such as were suggested by Cameron, Hurst and Kelly to explain spasm as an etiologic factor in producing dysphagia. In view of the well marked gross and microscopic lesions found in the pharyngoesophageal region in the specimen of his case "it seems unnecessary that hysteria be considered in the etiology of this disease." Recognizing the relation of simple achlorhydric anemia to this syndrome

Suzman states "The Dysphagia, it seems, is merely a complication or concomitant manifestation of this already well recognized form of anemia and there does not appear to be sufficient reason to regard this so-called 'Plummer Vinson Syndrome' as a separable clinical entity. From an etiological standpoint therefore, this syndrome may be considered simply one that may arise in idiopathic hypochromic anemia."

REPORT OF CASES AND COMMENTS

For the sake of brevity the accompanying table is given which illustrates quite graphically the principal points in the history, the physical examination, and the laboratory findings in seventeen cases presenting this syndrome, comments and further notes will be given in the text.

It is to be noted that all of these patients are

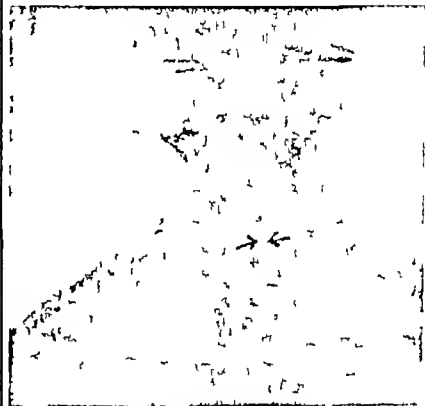

FIGURE 1. An anterior posterior roentgenogram of the upper end of the esophagus showing the narrowed portion indicated by the arrows. Case No. 9 in the table.

women. The average age for the seventeen patients is forty-six years, the oldest being sixty-three and the youngest thirty-two. Very few patients with this syndrome are found among men. Vinson reported twelve men out of sixty-nine cases, the highest per cent reported by any observer.

All of these patients complained of dysphagia and this symptom caused them to seek relief. The dysphagia varied from a marked effort to get food to pass through the esophagus to partial starvation because of this symptom. All the patients had a fear of getting food caught in the throat and choking spells. Therefore, the food was well masticated or prepared with grinders or sieves. Eating at the table with other people became impossible because they could not eat so fast and choking spells would be very embarrassing. This often forced them to eat in solitude and one busy woman did not have the

time it required to get an adequate amount of food. Fluids were frequently used to wash the food down or liquid food was taken.

Eleven of these seventeen patients presented themselves to the Clinic with the belief that they had thyroid disease which caused the difficulty in swallowing and on examination six had adenomatous changes in the thyroid gland coincident with the syndrome of anemia, etc., but in no instance could the thyroid enlargement account for the difficulty in swallowing.

Weakness, fatigue, shortness of breath and "no pep" were common to practically all. Gastric distress was present in two cases. Prac-

glossitis was not seen in any of these patients, and these patients did not have pain even on manipulation of the tongue. There was little complaint even though there were fissures present at the corners of the mouth.

Examination before the fluoroscope with the thick barium mixtures shows variation from slight hesitation to marked obstruction (see figure 2) at the upper portion of the esophagus.

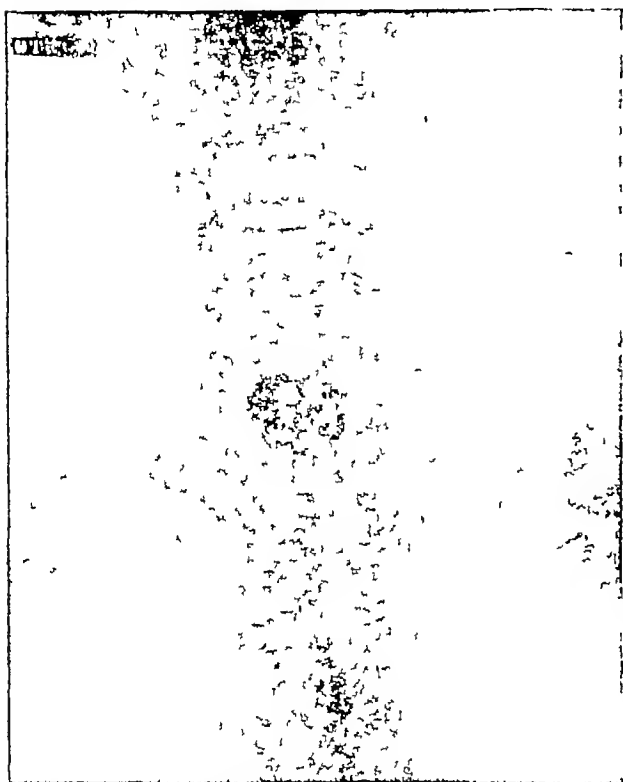

FIGURE 2 Anterior-posterior roentgenogram of the upper portion of the esophagus. Case No. 13 in the table showing narrowing at the region of the web.

FIGURE 3 Lateral roentgenogram of the upper end of the esophagus. Case No. 13 in the table showing the niche made by the web in the barium at the upper end of the esophagus.

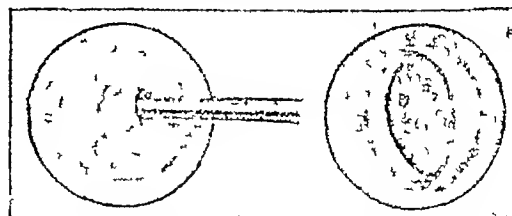

FIGURE 4a

FIGURE 4b

FIGURE 4 a the esophageal appearance of the web. Case No. 13 showing the opening in the web through which an instrument was passed and brought against the under surface of the web. The web was so thin that it was transparent. b shows the type of folds of partial web as seen in some cases. This one in Case No. 7 in the table. These webs are often attached to the posterior or lateral portion of the cricoid and pass backward around the upper end of the esophagus at the lowermost portion of the hypopharynx.

tically all had other positive findings which gave symptoms.

Anemia was known to be present by some of the patients and treatment had been given without results due to failure on the part of the patient to continue or because an inadequate amount of iron had been prescribed. None of the patients were apparently concerned by the presence of their anemia state.

Physical examination shows a patient of middle age or older with sallow skin appearing tired or fatigued and one is immediately impressed by the fact that the patient is below normal in general health and appearance.

The mucous membranes of the mouth and the conjunctivae are pale. The membranes of the pharynx are more dry than normal, slightly shiny and apparently thin. An actual acute

Examination with the esophagoscope and esophageal speculum shows the mucous membrane of the hypopharynx and esophagus similar to that of the pharynx. In two of the cases, no obstruction was encountered to the passage of the instrument. In four others a definite narrowing was present and pressure was necessary to pass the scope through the cricopharyngeal region and the upper inch of the esophagus.

gus This produced some cracking and abrasion of the membranes. Of these resistant cases, one required the passage of graduated dilators to produce an adequate lumen in the esophagus. In seven cases a definite band or web was seen at the upper portion of the esophagus. One web was so complete that it narrowed the lumen of the esophagus to about four millimeters and was so thin that one could see an instrument through it when placed against the under surface. (See figure 4a.)

The passage of the esophagoscope not only aids in the diagnosis but the dilatation produced by its passage relieves the dysphagia in most cases. Gastric analysis was made in eleven instances and in eight there was absence of free hydrochloric acid, in two there was a small amount, in one a normal amount. In seven cases an attempt to pass a stomach tube for gastric analysis was unsuccessful before dilatation. In six of these cases the attempt was repeated after dilatation with success. One patient would not permit the passage of the tube and in four others it was not attempted.

The spleen was palpable in two cases on routine abdominal examination. No special effort was made to palpate the spleen in any of the cases. The blood examination showed a hemoglobin varying between 29 per cent and 70 per cent. The red blood cells varied between 2,910,000 and 4,990,000 and the highest white blood cell count was 12,000 and the lowest 1,450. Measurements of the cells were not made but in some smears variation in the size and shape of the red cells was noted. Achromia was marked in practically all the smears.

As to the relation of anemia to the dysphagia it is my impression that the atrophic process predisposed to web formation and fibrosis, yet it is to be remembered that we see many cases who have the anemia but do not develop dysphagia and further that others develop webs and fibrosis without anemia.

The treatment consists of two parts the mechanical and anti-anemic. The dilatation can usually be carried out successfully at the time of the esophagoscopy examination but if this fails gradual dilatation can be carried out by passing dilators of gradually increasing size over the previously swallowed thread as suggested by Vinson in cases of esophageal stricture.

The dilatation which is so effective in relieving the dysphagia has very little effect on the anemia as was noted in case 10 in the table. This woman lived in a distant village. Her physician was instructed in carrying out her anti-anemic regimen but since she swallowed readily, and that having been her chief complaint, she neglected this part of her treatment. When seen one year later after a vacation on the beach where her diet was ideal and living conditions were excellent her hemoglobin was only 55 per cent.

Dysphagia may recur as further webs or bands may be formed and atrophic process continue especially if the anti-anemic treatment is neglected. Further dilatations will quickly relieve this symptom.

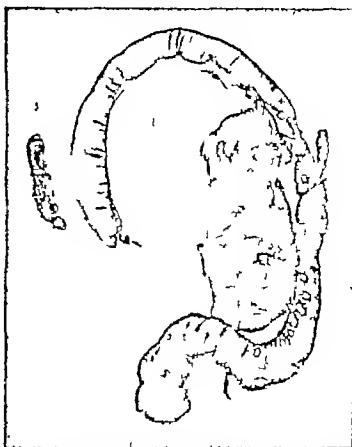

FIGURE 3. Microphotograph of a section made from the web in Case No. 13 which was removed from the esophagus with punch forceps. The web consists of two layers of mucous membrane with a small amount of fibrous tissue between them. The mucous membrane has separated partially from the fibrous tissue, especially in the lower portion.

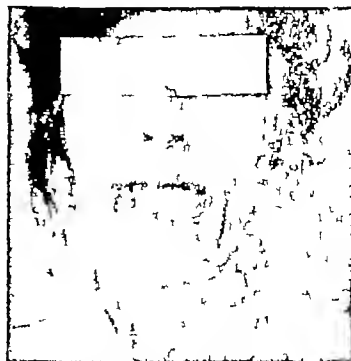

FIGURE 4. Photograph of Case No. 14 in the table, showing a smooth tongue and fissures at the corner of the mouth.

The anemia responds to the administration of iron salts in large doses. Murphy states that the optimal dose is that which supplies 500 mg. of iron daily and he finds ferrous ammonium citrate and ferrous carbonate the most effective of the iron salts, the dosage of 3 Gm. per day of the former and 5.4 Gm. of the latter will yield this amount. This dosage has been found satisfactory in our cases.

The treatment with liver alone is disappointing. Some early cases were given liver without a rise in the hemoglobin percentage. Following the use of iron in combination with liver the percentage of hemoglobin increased.

Murphy has found that the combination of iron (ferrie ammonium citrate) in adequate dosage with the intramuscular injections of solutions of liver extract (Lederle) produced the most rapid "improvement in anemia of the hypochromatic type." Once the hemoglobin has reached normal it is necessary for the patient to continue a diet with a high iron content: fresh fruits, green vegetables, liver, etc., or even take an amount of iron in the form of an iron salt in sufficient dosage to prevent a decrease in the hemoglobin of the blood and maintain the iron metabolism of the body. There is a great tendency in these patients once the dysphagia is relieved to forget to take the iron, and if the slightest abdominal distress occurs the patient gives the iron credit for the distress, the result being the discontinuation of iron medication.

Without careful follow-up the patient may not get a satisfactory increase in the hemoglobin or a relapse in the anemia may occur due to carelessness on the part of the patients. When difficulty in swallowing occurs it is so distressing that they seek further relief. In all the patients who have carried out instructions in medication there has been rapid increase in the percentage of hemoglobin. The anti-anemic treatment improves the appearance of the tongue as a rule. The fissures at the corners of the mouth rapidly improve without special attention being directed to them. In one instance the anti-anemic treatment relieved the dysphagia without the dilatations. This was in a young woman without severe dysphagia.

If there is obvious infection in the nose or mouth this should be cleared up.

Recently Hunter, Middleton, and Steenbock²⁸ have reviewed the recent writing on the atrophic tongue and with some experimental work and clinical investigation conclude that the smooth tongue most probably is due to a deficiency in diet or the inability of the patient to absorb Vitamin B. In view of this work I have given yeast to a few patients but cannot as yet make a definite report as to its efficiency.

SUMMARY

A brief review of the literature on the syndrome of anemia, glossitis and dysphagia is

given. The anemia is recognized as that reported as "Idiopathic Hypochromatic anemia" and so forth. The glossitis may more properly be described as an atrophic tongue and does not differ from that described in connection with other diseases. The dysphagia is often due to mechanical obstruction of the upper portion of the esophagus. Seventeen cases of this syndrome are reported. The treatment consists of mechanical dilatations and the prescription of iron salts in adequate dosage with or without liver. The need of careful follow-up is emphasized.

EPIDEMIC BENIGN MYALGIA OF THE NECK*

BY BENEDICT F. MASSELL, M.D.† AND PHILIP SOLOMON, M.D.†

THE purpose of the present paper is to report the high incidence in Boston during the past two months of a condition which appears to be an infectious myalgia of the neck. The attention of the writers has been forcibly attracted to this condition since each of us has suffered from it personally.

PROCEDURE

Three hundred individuals, chosen at random were questioned as to the presence during the past two months of "stiff neck", or "sore neck" in themselves or their immediate acquaintances. A majority of the persons questioned were doctors, nurses, and hospital employees, but members of other walks in life were also included. Adults only were chosen, the age variation being roughly twenty to seventy years. When an individual was encountered who had had the symptoms in question, the following data were ascertained: date of onset (as well as could be remembered), time of day of onset, location, severity, and duration of the symptoms, interpretation of cause of the symptoms, incidence of such symptoms in the past, and the treatment employed.

RESULTS

Of the 300 individuals questioned, fifty-two (17.3 per cent) had the symptoms in question within the past two months. The time of onset is shown in figure 1. It can be seen that an accurate recollection of the date of onset was rarely available after an elapse of two weeks or more. Answers such as "about two months ago", "last month" and "two weeks ago" were frequently obtained. It is probable that were the exact date of onset known in each case the distribution would be more even.

In addition to the fifty-two positive cases personally interviewed, the authors have knowledge of sixty-one other cases of "stiff neck" which have occurred in Boston within the past two months. Twelve of these came to the Out-Patient Department of the Boston City Hospital with pain and stiffness of the neck as their chief complaint. The remainder were relatives or friends of the group interviewed. It is probable that these cases represent only the more severe ones, many more may have been present among the acquaintances of the group inter-

viewed, but were not severe enough to warrant their talking about the trouble.

The description of a typical case follows.

The patient, a physician was awakened from a sound sleep at 5:00 A.M. on June 26 by a severe pain in the left side of his neck. The pain was neither dull nor sharp but somewhere between the two. It was definitely made worse by motion especially by rotating movements of the head. It seemed to be deep in the tissues of the neck near the occiput. Palpation elicited no single spot of localized tenderness but deep pressure was very painful over the whole left side of the neck, along the border of the trapezius muscle and especially just below the occiput. The patient was unable to lie comfortably in any position and could not fall asleep again. He interpreted his symptoms as possibly

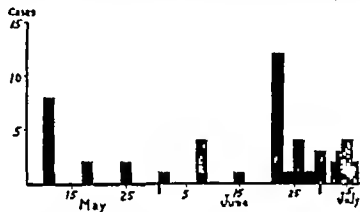

FIGURE 1 The date of onset of 5 cases of myalgia of the neck, May-July 1935

being due to a subluxation of a cervical vertebra which somehow occurred in his sleep. Several hours later he consulted a surgeon, who examined him carefully and thought that the condition was myositis, chiefly of the trapezius and splenius muscles. The pain had diminished somewhat, but the tenderness was unchanged. There was no malaise, headache, fever or other symptoms. Baking and massage were recommended but the patient, with the typical lax attitude which physicians often take toward the treatment of their own illnesses, did nothing. The next day the pain had almost entirely disappeared but rotating movements of the head were still quite painful especially to the left. The third day the pain was gone but could be brought back by extreme rotatory movements of the head to the left. The condition has persisted at this stage to the present (July 6).

The case described above was perhaps more severe than the average, although many were severe enough to be incapacitating for the first twenty-four hours. In almost every case, the patients were in perfect health at the time of onset of the symptoms. The nearly complete absence of associated symptoms was remarkable. The patients were not ill, in only a few cases was headache present, appetite was not interfered with and sleep was prevented only in the rare case where the pain persisted and was sufficiently severe to make the assumption of a comfortable position impossible. In the great majority of the cases the symptoms were first

From The House of the Good Samaritan, The Neurological Unit, Boston City Hospital and The Department of Neurology, Harvard Medical School, Boston, Massachusetts.

*Benedict F. Massell—Resident Physician, House of the Good Samaritan. Philip Solomon—Assistant in Neurology, Harvard University Medical School. For record and addresses of authors see "This Week's Issue," page 422.

noticed on awakening in the morning. In a few instances the symptoms were practically gone by noon, but in most cases they persisted for twenty-four to forty-eight hours, and then continued in a mild form for several days or weeks thereafter. Recurrences were not uncommon, but were never so severe as the original attack.

The location of the pain can best be explained by referring to figure 2. The pain was uni-

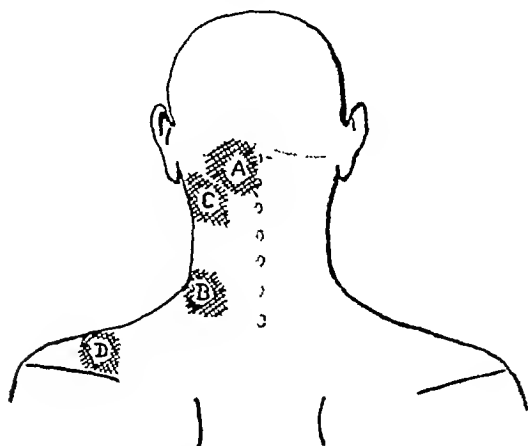

FIGURE 2 The common locations of the pain in myalgia of the neck. For explanation see text.

lateral in almost every case. The left side was somewhat more frequent than the right. The favorite site for the pain was at A, just below and to the side of the occiput, along the origin of the trapezius muscle at the superior nuchal line. The next most common site was at B, halfway down the neck along the border of the trapezius muscle. Other sites for the pain were at C, the insertion of the sternocleidomastoid muscle, and D, the lower border of the trapezius at the shoulder. In a few cases the patients thought they had a sore throat until they realized that the pain was not in the throat but deep in the muscles of the neck. One patient had very deep-seated pain accompanied for a short time by pain on swallowing. In the cases examined, nodules or extremely localized tenderness could not be felt. The pain often was more generalized in the side of the neck than is shown in figure 2. Movement of the involved muscle invariably caused severe pain, so that the patients were wont to walk about "stiff-necked", turning the whole body rather than the head in order to look to the side.

The interpretations which the patients gave for the cause of their symptoms were interesting. The majority said, "I thought I must have twisted my neck somehow in my sleep." Others thought they "must have been in a draught" the day before. A few thought that physical activity, such as swimming or tennis, was the cause. Two surgeons thought that a strained position during prolonged operating the day before might have been the cause. It is significant that no one of these patients has been subject to

"stiff neck" in the past, or has had this symptom commonly after activity similar to that which he thought might be the cause of the present condition.

The treatment used in the severe cases was heat and massage. Diathermy, infra-red baking, and a variety of liniments were occasionally employed. The heat in every instance seemed to give a measure of immediate relief. The massage, while extremely painful, was followed by a more lasting relief. It is doubtful how much good these measures were for the underlying condition. The cases without treatment ran approximately the same course as those with treatment. No complications occurred, and all cases recovered without residuals.

COMMENT

The high incidence of this condition (greater than one in six) demands attention in spite of the obvious benign character of the symptoms. It is possible, though it would seem unlikely, that at any time of the year one could elicit this same proportion of similar symptoms within the previous two months. If this were so, the fact would be even more interesting and more demanding of further research. It is possible that the explanations offered in the individual cases for the symptoms are indeed the correct ones. But the commonest of these, exposure to draughts on the previous day, has long been the layman's explanation for the onset of the common cold, the true etiology for which is now known to be infectious. A hypothetical twist of the neck during sleep seems hardly plausible enough to warrant serious consideration. Besides, several cases occurred during the day while no physical activity was going on. Physical exertion the previous day, swimming and tennis, admittedly popular at this time of the year, could be offered as an explanation in only a few cases, and in these it was unusual and surprising to the patients to find such acute symptoms as the result of physical activity which was not uncommon to them.

It seems to us quite possible that the etiology of the condition in question is on the basis of an infectious agent. While we are not in a position to offer proof for this hypothesis, there are several considerations which are in its favor. These are the apparent epidemic nature of the condition, the uniformity of the onset, symptomatology, and course, and the absence of other apparent causes. In two instances in this series, patients reported that their wives complained of symptoms similar to but milder than theirs on the day following the onset of their own symptoms. Aside from these instances, there seemed to be no other multiple cases in the same family.

Conditions similar to that described in this paper have been frequently discussed in the

literature under the name of "fibrositis", "myalgia", "myositis", or "muscular rheumatism". Most of the authors have been interested chiefly in the chronic or recurrent form, and particularly in association with articular rheumatism. Very little attention has been given to the acute forms. Epidemics of acute pleurodynia or Bornholm disease have been reported², but no reference can be found to epidemic myalgia of the neck. Except for brief discussions in the textbooks, the American physicians have almost entirely ignored the question of muscle pain.

"Stiff neck" has probably always been a common complaint, and the attitude of the public toward it has been one of annoyed tolerance and resignation, much the same as its attitude toward the common cold. But the total amount of pain and suffering occasioned in the community by these minor illnesses is enormous. Further research into the etiology of these conditions is obviously indicated.

SUMMARY

The high incidence in Boston during the past two months of a condition which appears to be

an infectious myalgia of the neck is reported. Of 300 individuals questioned, fifty-two, or 17.3 per cent, had the symptoms in question. The condition is described and attention is called to its apparent epidemic nature at present.

COEXISTING INTRAUTERINE AND EXTRAUTERINE PREGNANCY

BY HENRY H. FAXON, M.D.*

COEXISTING intrauterine and extrauterine pregnancy is an unusual although not extremely rare finding. The first reported instance of this condition was recorded by Davenport in 1708. His diagnosis was made at autopsy the mother having died in the third month of pregnancy as a result of rupture of the extrauterine sac.

A number of efforts have been made to correlate separately reported cases and three exhaustive reviews of articles dealing primarily with the group as a whole have been published by Novak (1926), Stein (1928) and Gemmell (1933). Although there are certain minor differences in these reports, due chiefly to each author's discrimination as to which published cases should be included in his series and to the time of publication, they agree essentially as to the findings derived from statistical evidence. As a matter of interest the following observations, based on the above reviews, are given by way of introduction.

There have been approximately 250 cases of coexisting intruterine and extrauterine pregnancy reported. Ten per cent of these might well be excluded as representing instances of intruterine pregnancy superimposed upon a tubal or intra-abdominal pregnancy that oc-

curred from one month to many years before. Thus, the finding of a lithopedion in conjunction with a normal gestation represents what has better been termed a "compound" than a "combined" pregnancy. In all save the ten per cent noted, impregnation of the tubal and of the uterine ova took place presumably within a short time of each other. In no instance has there been convincing evidence to show that ectopic conception occurred after intrauterine pregnancy was established.

In sixty per cent of the cases the mother was between the ages of twenty-five and thirty-five years, with slightly more than half of these cases falling in the latter five-year period.

Thirteen per cent of the cases occurred in nulliparae while fifty-four per cent of the women had previously borne one, two or three children. In six of the cases there was a history of previous multiple intrauterine pregnancies, but save for this finding no evidence was advanced to show any causal relationship between previous pregnancies and the occurrence of coexisting intruterine and extrauterine pregnancy.

The symptoms complained of early in the course of the condition were usually attributable to the tubal pregnancy, while those in the latter months were more commonly the result of the intruterine gestation. The condition was

*Faxon Henry H.—Staff Assistant Surgeon, Massachusetts General Hospital. For record and address of author see "This Week's Issue," page 432.

ed, it does not appear that the septum had undergone any morbid degeneration, which could be thought to give it a greater liability to rupture than any other part of the heart's muscular structure. But such degeneration was so remarkable in the case which had fallen under my own observation that I could not help desiring a more accurate examination of the preparation of St Bartholomew's, if after the lapse of seventeen years it were indeed possible. Mr Paget and Dr Ormond undertook it for me, with the aid of the microscope, and have obligingly communicated to me what they were able to make out. 'There was much oil swimming on the top of the jar. The texture of the heart was somewhat soft. On the parts about the rupture were many drops of oil, and hereabout the muscular tissue was evidently disorganized, for it appeared as irregular granular cords, without any transverse striae, which elsewhere were well marked. But there was no distinct fatty degeneration of the muscular fibres.'

"It appears then that in this, as in the other case, the septum had undergone a morbid change of structure, rendering it more liable to suffer rupture. But the change was not exactly of the same kind in the two cases."

The primary importance of the sclerosis of the coronary arteries was not fully appreciated, however. Dr Herrick, of Chicago, beginning about 1912², took a leading part in pushing recognition of the disease in its entirety. The first diagnosis made in Boston before death, and proved at autopsy was as late as 1916³. Dr Samuel Levine's monograph, published in 1929⁴, gives excellent descriptions of the disease, and outlines treatment.

The frequency of coronary occlusion has been somewhat of a surprise to me. It seemed worthwhile at the completion of five years of community practice in an outlying portion of Boston, to compare its occurrence with that of a few other diseases of major importance.

Twelve hundred and sixty-five patients have been treated in the five years. Thirty-nine of these have died while under my care, the primary causes of death being as follows:

Coronary occlusion	9
Malignant neoplasm	7
Chronic myocarditis	5
Lobar pneumonia	5
Arteriosclerosis, generalized	4
Cerebral hemorrhage	4
Bronchopneumonia	3
Chronic nephritis	1
Cystitis and pyelitis	1
Intestinal obstruction (old adhesive bands)	1

There have been seven autopsies in this group of thirty-nine deaths.

Coronary occlusion has been the greatest single cause of death in this series, constituting nearly a fourth of the total. If the cases in which the patient had died suddenly, before I saw them, and which had not previously been under my care, were to be included, the proportion would be somewhat higher. For in a large share of such instances, the story as given by onlookers is apt to be typical of coronary occlusion.

Among patients who live, as well as among those who die, coronary occlusion is common. The number of patients encountered having as their chief disease one of an arbitrarily chosen group of fifteen major conditions is listed below. These are all patients who were alive while under my care, so are in addition to the group listed above.

Chronic myocarditis and hypertensive heart disease	32
Diabetes	24
Coronary occlusion	15
Rheumatic valvular heart disease	11
Peptic ulcer	11
Tuberculosis	11
Syphilis	11
Malignant neoplasm	10
Cerebral hemorrhage	8
Acute nephritis	7
Pericious anemia	6
Lobar pneumonia	5
Acute rheumatic fever and chorea	4
Hyperthyroidism	4
Chronic nephritis	3

Coronary occlusion ranks third in frequency in this list. The two groups containing larger numbers, viz (1) chronic myocarditis and hypertensive heart disease, and (2) diabetes, include many individuals who in future years will have cardiac infarction.

Of the total of twenty-four cases of coronary occlusion, nine died of the disease while under my care, two died of the disease while under the care of others, and one died later of malignant neoplasm. The remaining twelve are in fair or good health. Five of the eleven deaths from the disease occurred within the first two weeks following the initial occlusion.

The history alone will give an accurate diagnosis more often than not. In most cases it is a history primarily of crushing pain in the front of the chest. There are variations. One woman complained of sudden and terrific pain in the upper dorsal spine. The first day she consistently denied even the slightest pain or heaviness in the front of her chest. But on the second she said that the front of her chest felt a little freer than it had the day before. Vomiting is not uncommon as a prominent complaint, the "acute indigestion" which we still hear mentioned by laymen, and even by physicians.

When seen within a few minutes or a few hours of onset, as the community practitioner is apt to see these patients, the only physical sign

of value may be the drawn or pained appearance of the face. The temperature, pulse and blood pressure are frequently at their usual levels. But a careful history, carefully appraised, may in fifteen minutes make a reliable diagnosis. The appearance during subsequent hours or days of slight fever, leucocytosis, faster heart rate, drop in blood pressure, precordial friction rub, congestive failure—or even sudden death—will usually confirm the original diagnosis. In only an occasional instance does an electrocardiographic tracing contribute any more toward a sound diagnosis than the history and the ordinary bedside findings. In a few cases in which symptoms, and even the signs are strongly suggestive of an acute abdominal condition, an electrocardiographic tracing may be of paramount importance.

Since in most cases the diagnosis can be made at the bedside, perhaps with the aid of leucocyte counts at the physician's office, hospital

ization is seldom necessary for diagnosis. And it is seldom essential for treatment. Usually it is to be preferred that the patient be kept at home, and not moved. Other members of the family, or a nurse, can give closer attention to the patient than would be given in a hospital, unless special nurses are provided.

SUMMARY

1 Coronary occlusion is a common disease in community practice

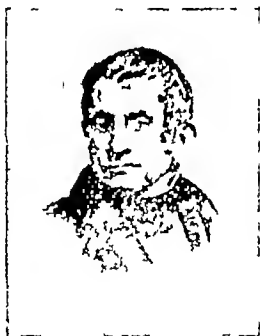

2 Diagnosis and treatment can in most cases be carried out satisfactorily in the home, relieving the burden on hospitals

JACOB BIGELOW, M.D., LL.D.*

BY CHESTER D. STELLHORN, M.D.†

JACOB BIGELOW

Generous soul

Whose high ambition marks a loftier goal
Whose settled eye awaits a distant scene
Heedless of narrow fields that intervene
His sure resolve and firm unbending soul
Nor luring hopes, nor threatening fears control
Fixed in the high but rough ascent to fame
With ardent step and undivided aim
Nor bars nor years his progress can abate
Firm to excel and patient to be great.

ON May 27, 1835 at the annual meeting of the Massachusetts Medical Society, Jacob Bigelow delivered a discourse on "The Self Limited Diseases." The clarity, simplicity and timeliness, together with the quaint and gentle humor of the paper, perhaps explains the profound effect

From the Department of Surgery, Cumberland Hospital, Brooklyn, N. Y.

*Stellhorn, Chester E.—Resident Surgeon, Cumberland Hospital, Brooklyn, New York. For record and address of author see "This Week's Issue," page 422.

which it exerted. Dr. Oliver Wendell Holmes wrote "This remarkable essay had more influence on medical practice in America than any other similar brief treatise." It was directed against the universally exaggerated faith in drugs and the heroic therapy of the day. In popular opinion Homeopathy has the credit for bringing about that radical change in therapeutics. Bigelow's paper, however, was actually responsible for the reform.

The author, Jacob Bigelow, was of old New England ancestry. His people came to this country in 1640 and settled in Watertown, Massachusetts. He was born in 1787, graduated from Harvard in 1806, attended medical lectures there in 1808 and graduated from the Medical College of the University of Pennsylvania in 1810. There he studied under the eminent Benjamin Rush who was want to say to his students, "We can have no reliance on nature gentlemen. We must turn her out of doors in our practice and substitute for her effluent art." These were not the ideas of Bigelow as we shall see.

He began to practice in Boston by an association with the elder James Jackson. Years later, when he was asked how, without our modern medical schools, hospitals and clinics he obtained his professional training and knowledge, he replied, "Oh from my patients." To bring himself before the public he began to write and won the Baylston prize for four successive years.

Botany was his great hobby. In 1812 he gave a public course of lectures on botany to the citizens of Boston. His "Flora Bostoniensis" published in 1814 was very popular. In 1815 he was made a lecturer on Materia Medica at Harvard and in 1817 he was made Professor. Under

the title of "American Medical Botany" Bigelow published an elaborate series of volumes during the years from 1817 to 1820. This brought him European recognition. The preface to this work contains the germ of many of the ideas which he later elaborated. "Much harm has been done in medicine by the partial representations of those, who, having a point to prove, have suppressed their unsuccessful experiments and brought into view none but favorable facts." Photography and lithography were then unknown and Bigelow invented for his purpose an original method of printing in colors directly from copper plates. The illustrations, some sixty plates and over 6,000 engravings, were all made by Bigelow. Their exquisite workmanship, accuracy and artistic arrangement would grace with distinction a modern herbal. The volumes have become quite scarce and are much sought by collectors.

He became an excellent craftsman in many lines. It is said that he went to every shop, cellar and garret in Boston where the mechanics would allow him and would answer his questions. "He knew what was done and how done by smith, glassblower, clock maker, type caster, printer, moulder and engraver." These forays yielded the material for his early lectures on the application of science to the useful arts. They also lent direction to his tastes and views and led to his participation as a founder of the Massachusetts Institute of Technology.

Bigelow lived to be ninety-two and his long life was crowded with many achievements of the highest order. He was the first Rumford Professor of the Application of Science to the Useful Arts. He assisted in the editing of the first edition of the United States Pharmacopoeia, following this with "Bigelow's Sequel," a commentary on current remedies. During the great cholera epidemic of 1832 the death rate in Boston was the lowest of any of the large cities on the Atlantic seaboard, due to the wise adoption of the rigid sanitary precautions urged by Bigelow. He was a visiting physician at the Massachusetts General Hospital and had a large consulting practice. From 1842 to 1847 he was president of the Massachusetts Medical Society, having served previously as treasurer from 1823 to 1828.

Three other achievements were outstanding. In 1825 the dead of the cities were still being buried in churchyards or in vaults. The matter became a serious one, the churchyards were full and the danger to public health was great. Bigelow wrote a series of papers during the years from 1825 to 1832, urging his plan for a forest garden cemetery outside of the city. A storm of opposition and ridicule met this proposal. Bigelow met this criticism, supplemented his statements and where necessary, defended them. Here as in other battles, he carried his own cause. In spite of continuing dissent, the Mount Auburn Cemetery was dedicated for public use

in 1832. In a very true sense Bigelow was the founder of this first modern cemetery. "He laid out the grounds, thinned the trees, surveyed roads, paths and hedges, he supervised the ornamentation. He designed its classic gateway and approach. He became the first of our landscape architects."

Bigelow was also an educational reformer. In 1865 he delivered an address on the "Limits of Education" at the opening of the great hall of the Institute of Technology. His object was to break rather than extend the limits. He believed that education should be extended from ancient and classic lore to the recognition that scientific studies, modern languages and learning also constitute education. He placed the culinary art beside music and painting. He asked, "Why should not a refined and cultivated anesthesia be so varied in its applications and degrees as to exempt mankind from their griefs and grievances by an artistic application?" All this is commonplace today but caused widespread discussion at home and abroad at the time. Just how much we are indebted to Bigelow for our modern college curriculum is very difficult to determine. Doubtless, he was but one of many who argued for this reform.

His most important paper was that entitled "Self Limitation of Diseases." The medical profession needed this confession of past error and the acknowledgment that it might still be wrong and be experimenting in the dark. "Medical books," he says, "are prompt to point out the cure of diseases. Medical journals are filled with the crude productions of aspirants to the cure of diseases. Medical schools find it incumbent on them to teach the cure of diseases. The young student goes forth into the world, believing that if he does not cure disease, it is his own fault. Yet when a score or two of years have passed over his head he will come at length to the conviction that some diseases are controlled by nature alone. He will often pause at the end of a long and anxious attendance and ask himself how far the result of the case is different from what it would have been under less officious treatment than that which he pursued, how many in the accumulated array of remedies which have supplanted each other in the patient's chamber, have actually been instrumental in doing him any good. He will also ask himself whether in the course of his life he has not had occasion to change his opinion, perhaps more than once in the management of the disease in question and whether he does not, even now, feel the want of additional light."

He anticipated and answered the questions, "Is there then no need for a physician?" "Shall he then in any case stand by and do nothing, prescribe nothing?" The preventing of the doing of some things, he says emphatically, is often the highest form of service. There is also abundant use for the physician "in the discriminating study of a case, in careful interpretation of na-

ture, in coöperating with it, in soothing and palliating appliances, and in averting incidental aggravations of disease. Besides this, science has really accomplished something." Homeopathy he likened to this side of medical practice which without interfering, awaits expectant on its unassisted course. This is the real reliance of Homeopathy though not its avowed one. Bigelow was tolerant of the doctrines of Hahnemann. "A certain portion of mankind," he says are so constituted that they require to be ridden by others and if you should succeed in unhorsing a particular impostor, it is only to prepare the saddle for a fresh and more unflinching equestrian."

So rapidly was the change effected that today there are only traditions of the old methods of heroic treatment and blind submission to dogmatic therapy. One would like to conjecture as to the effect of these opinions upon the mind of Henry J. Bigelow, the son of Jacob and wonder whether they were the force which impelled him to embrace the surgical side of the healing art.

In old age Bigelow amused himself by writing "Chenodia," a Mother Goose rendered in Greek and Latin. With his wife and friends he took a

sightseeing trip to California. He had a whole some interest in political events for he had been the friend of John Adams, Thomas Jefferson, Daniel Webster, Lincoln and Grant. His son became a famous surgeon in Boston. He who had been the Nestor of his day became a distinguished, approachable, old man oracle. He remained modest and unassuming. Blind and bedridden for the last five years of his life he was unforgotten to the very end. He died Jan. 10, 1879.

The poem quoted at the beginning of this biography is the Phi Beta Kappa poem, written by Jacob Bigelow and delivered at Cambridge in 1811. It is truly a self portrait.

VERMONT STATE MEDICAL SOCIETY

IRRADIATION TREATMENT OF TUMORS*

Late European Developments

BY C. F. BALL, M.D.,†

SINCE I grew up with the therapeutic development of x rays and radium, I naturally had a keen interest in the Fourth International Congress of Radiology, and a special interest since a prominent part of the program of that Congress was to be a résumé of therapeutic techniques as used by the important clinics of the world. When I was invited to accompany the American Delegation to Switzerland I felt particularly honored. I found the Congress to be all that I had expected, and more. One of our American delegates stated that "undoubtedly it was the largest gathering of the leading Radiologists ever assembled in the world."

The American Delegation was royally entertained by the British radiologists for a week in England, at London, Cambridge, and Teddington. The British delegation then joined the American group on the trip to Eindhoven, Holland and up the Rhine through Germany to Zurich. This trip by buses from the Hook of Holland took several days, with stops at most of the important radiological clinics. The German radiologists, like the British, demonstrated their equipment and freely gave detailed data as to their various techniques. Therefore my re-

mains in so far as the Congress is concerned, will reflect not only what was presented in therapeutics at Zurich and St. Moritz, but also what was learned en route. To me, each was of equal value.

Irradiation techniques fall into two general groups: Regulative and Destructive. The former are applicable principally to benign processes or lesions encountered in medicine. The destructive techniques are more specifically applicable to malignant neoplasms or malignant functional processes encountered in surgery.

Perhaps the most important single statement made relative to the general subject of irradiation therapy was made by Professor Schulz, President of the Congress, in his introductory address. When speaking of the relation of surgery and radiology, he said: "It is clear that Surgery and Radiology have their indications, strict indications, and these indications should not be forgotten in favor of a personal preference. *Even more harmful can be a separation of deep X Ray therapy and Radium therapy.*" Irradiation should never be thought of in terms of either agent alone. X rays are frequently ineffective of themselves, but when combined with proper radium dosage the two become admirably efficient. The same is true of the uses of radium, except in unusual amounts.

*Read at the Annual Meeting of the Vermont State Medical Society, Burlington, Vermont, October 4 and 5, 1934.

W M Levitt⁹ at St Bartholomew's Hospital, London, developed a modified Coutard technic

"(1) To provide an intensity of radiation on the esophagus comparable with that obtained by the technic in use for the treatment of similar growths in the throat

"(2) To provide a daily dose to the esophageal growth which should equal as nearly as possible that obtained by a similar growth in the throat treated by the usual technique

"(3) In addition, it was considered important that a sufficient span of esophagus above and below the growth should be included in the irradiation because of the known tendency of the disease to spread up and down the esophagus "

General consensus in Cancer of the Breast is that *all malignancies of the breast should be preoperatively irradiated*. Transirradiation of the breast mass should be employed as much as possible, thus avoiding the thorax to a considerable extent. There are axillary nodes and some supraclavicular nodes that often can be more successfully attacked with radium than with the x-rays. X-rays are more applicable to the larger areas of the chest. In a few weeks after the treatments, operative removal may be used in suitable cases, such cases being those where complete regression of the secondary glands occur. Then a Halstead operation is indicated. Otherwise there seemed to be a general feeling that it is best not to explore an axilla with persistent nodes, following irradiation, since such surgery would definitely aggravate an otherwise partially or completely arrested activity. Breast statistics are at best bad, by any or all methods of therapy. Early diagnosis and early treatment have not seemed to be too effective.

Primary carcinomatosis of the lungs or bronchial primary carcinomata are dealt with rather more conservatively as to individual indications, but such modified treatments are made to extend over longer periods of time.

It is now felt that longer and smaller dosages per treatment, continued over longer periods of time, effect more mitotic cell divisions and so ultimately kill off more cancer cells than the big single dosage therapy of a few years ago. Perhaps more accurately it helps to build up a defense mechanism which of itself limits the diseased process. There are many experimental data to substantiate this latter position but I cannot go into it further at this time.

Adenocarcinomata of the intestinal tract are not successfully treated as a general rule. Now and then there is a favorable case, which goes to indicate that a therapeutic trial should be made. It should be followed up if the tissue is radiosensitive, abandoned if resistant. A few treatments only are needed to determine which is which. Some clinics irradiate through the open wound direct to the tumor mass. In this particular class of cases close association with

early surgery is imperative. *Only as abdomens are explored on a reasonable suspicion of probable malignancy can this form of disease be helped*.

Some slight progress seems to have been obtained in the protracted type of irradiation therapy in cancer of the rectum and prostate. Most of these cases are seen too late.

Preoperative irradiation is advisable in all tumors of the kidneys, since irradiation does not seem to damage the renal epithelium of a glomerulus or of the tubules. It does, however, reduce the size of the tumor by its effects upon the embryonal and sarcomatous forms of tissue found in many of the kidney tumors. After their reduction in size and cellular inhibition, they are then more safely removed surgically. The irradiation does not increase the surgical difficulties of the nephrectomy. This applies to the three types, hypernephromata, adenocarcinomata, as well as the mixed tumors of the kidneys. Not all respond favorably since some have a large amount of fully developed radio-resistant epithelium. If the tumor does not subside with a good course of irradiation promptly, stop treatment and do a nephrectomy at once. Irradiation will often make an otherwise hazardous operation safe.

Irradiation has raised the curability of cancer of the cervix from less than 15 per cent by the older surgical procedures, with a 50-50 operative mortality, to about 50 per cent curability and this without any appreciable mortality. Moran¹ in his paper "Some Opinions Based on Cancer Work in Australia", states the following concerning cancer of the cervix: "Two facts stand out. One is that such menopausal bleeding is not often an early sign unless it be the slight 'show' which follows the marital act. Secondly, a lack of faith in the capacity of medical men to effect a cure leads the sufferer to postpone consultation, for she prefers to live in ignorance rather than to be definitely informed that she has what she believes to be an incurable disease. The attitude of many practicing doctors who do not appreciate the notable advance made in the treatment of uterine carcinoma is chiefly responsible for this, their lack of optimism filters through to the lay population." "What parallelism exists between the increased incidence of uterine cancer and the increased use of chemical and mechanical contraceptives, it is difficult to say, but the subject invites careful enquiry." Statistics shown from Stockholm indicated that present technique was about as effective as the clinical appearance of the disease allowed, 70 per cent cures in grade 1 cancer of the cervix, about 50 per cent in grade 2, and only about 20 per cent in grade 3 and practically none in grade 4 cases. No alteration in techniques had seemed to improve their figures in the past five years. Grades 1 and 2 are the most hopeful. Physicians

should remember that grade 1 is practically non clinical, found only on routine biopsy, and grade 2 is only suspicious or very early clinically, grade 3 is readily recognized clinically and too late for good results, grade 4 is grossly apparent and almost hopeless.

Up to recently, cancer of the fundus was thought best removed surgically. Several authors at this Congress gave statistics that indicated that irradiation was frequently as effective as surgery, without the usual surgical mortality risk.

Chorionepitheliomata and some of the teratomata are radiosensitive. The required extent of irradiation therapy in these tumors may be determined by the Aschheim Zondek Test.

Epitheliomata of the penis and vulva come under skin lesions already referred to, but are far more difficult to treat than similar lesions on exposed surfaces because the associated glands have to be treated the same as metastatic cervical glands, with heavily filtered protracted irradiation.

Metastatic bony lesions in some instances respond to irradiation therapy. Primary bone tumors are usually very resistant and a therapeutic test should be made in all cases. The problem of bone tumors is difficult from any angle. Osteoporosis of endocrine origin is benefited by irradiation to bone lesions and endocrine glands involved, usually the parathyroids.

SUMMARY

The international scope of the Congress of Radiology was fully expressed by the large number of different countries represented on the program.

The experimental, physical, and clinical papers were thoroughly international in character and all in general accord. Particularly was this true relative to the clinical application of irradiation therapy. Many techniques were quite thoroughly standardized at least in principle, if not always in exact physical relations. There was a very definite trend in the use of radium away from interstitial (needling) irradiation to surface applications, more highly filtered and at greater distance from the surface, and applied for longer periods of time. Continued absorption of irradiation energy from either source by malignant tissue over longer periods of time seems more effective than the shorter and more intensive methods of a few years ago. In general the x ray beam is being more highly filtered and given at a more moderate milliamperage, over many more total hours of application than formerly. Work with the ultra high x ray voltages is still experimental. Efforts are being made to perfect apparatus that is capable of measuring both of these irradiation beams in a common unit of energy of absorption.

As a result of these changes, better and better statistics of the curability of cancer are be-

ing recorded by the various countries, with each in closer accord one with the other.

Modern irradiation methods add a definite hope to many a cancer sufferer. The general practitioner should reflect this hope in his attitude to his patient.

MISCELLANY

VERMONT DEPARTMENT OF PUBLIC HEALTH

JULY 1935

During the month of July the incidence of communicable diseases, as reported to this Department is as follows: chicken pox 36 diphtheria 1, German measles 236 measles 187 mumps 39 scarlet fever 16 undulant fever 1, typhoid fever 1, whooping cough 125 and tuberculosis 15.

The Laboratory of Hygiene reports a total of 188 examinations made in July. The results are as follows:

Examinations for diphtheria bacilli	73
Widal reaction of typhoid fever	51
" " undulant fever	71
" " gonococci in pus	146
tubercle bacilli	159
syphilis	513
of water chemical and bacteriological	209
" water bacteriological	234
milk market	208
milk, submitted for chemical only	0
milk, submitted for microscopical only	0
" foods	10
" drugs	0
" for courts autopsies	2
" " courts miscellaneous	23
" of animal heads for evidence of rabies	1
" for presence of malaria	2
" miscellaneous	61
Autopsies to complete death returns	1

Thirty seven cases of gonorrhea and eleven cases of syphilis were reported to the Division of Communicable Diseases. This Division mailed 638 Wassermann outfits and 342 slides for gonorrhea.

The Sanitary Engineer visited several towns inspecting sewage systems water supplies and camps. The Sanitary Engineer also made a survey of one of the lakes in the state.

The State Advisory Nurse of the Division of Public Health Nursing has devoted most of her time during the month of July to concluding the work of the VERA, having received word that the work of public health nursing was closed

RECENT DEATH

BLODGETT — JOHN H BLODGETT, M D, of Bellows Falls, Vermont, died suddenly August 2, 1935. He had been in poor health for a long period. He was born in Grafton, December 31, 1867, the son of Henry and Jane (Ayers) Blodgett. His premedical education was acquired in the public schools of Grafton and Chester, and in the Vermont Academy. He matriculated in the University of Vermont and after receiving the degree of Bachelor of Philosophy in 1895 entered the medical school and his M D degree was conferred in 1897. His internship of two

years was served at the Boston City Hospital. He first settled in Saxtons River in 1899 and in 1908 he moved to Bellows Falls, where he built up a large practice. Dr Blodgett served as representative and senator from his county, and was chairman of the State Tuberculosis Commission for a time. He formerly served on the State Board of Registration of Nurses. In addition to membership in the Windham County and State Medical Societies, he was a Fellow of the American Medical Association. He served on the Staff of the Rockingham Hospital and was also a trustee and member of the executive board of this institution. Another medical activity was that of attending physician to the Kurn Hattin Homes. He was a Mason, a deacon of the United Church and affiliated with the Delta Mu college fraternity.

Dr Blodgett is survived by his widow, Mrs Mary L (Abercrombie) Blodgett, formerly of Boston.

HOW GRIEVANCES ARE DEALT WITH UNDER THE ENGLISH HEALTH INSURANCE SCHEME

BY G F MC CLEARY M D ‡

THERE are 16,071,000 men and women in England and Wales insured under the national health insurance scheme, and there are 16,500 insurance doctors. The insured persons, having paid their contributions to the cost of the scheme, are entitled to receive proper medical treatment, the insurance doctors by virtue of their agreements with the local Insurance Committees are under obligation to give it*, and the Insurance Committees and the Ministry of Health are responsible for ensuring that the doctors' obligations are fulfilled. Where medical services are provided on so enormous a scale, it is inevitable that cases will occasionally arise in which an insured patient considers, rightly or wrongly, that he has not received proper treatment from his insurance doctor, and it is necessary that a procedure should be devised by which such grievances shall be dealt with equitably, expeditiously, and economically.

In some European countries the doctors' obligation to give proper and necessary medical services is enforced by the insurance authorities' selecting the insurance doctors and making them responsible to superior officers for the quality of their work. Failure to do good work may result in the termination of the doctor's appointment. Under the English health insurance scheme there is no selection of doctors by the

insurance authorities. Any doctor†, however careless, intemperate and incompetent he may be, has the right to join the local panel of insurance doctors, and he has no superior officer to supervise his work. Some safeguard has been provided by giving the persons insured under the scheme the right, which private patients have, to choose, and change, their doctors, a doctor who acquires a reputation for bad work will sooner or later see his list of patients grow smaller and the lists of his competitors larger by the transfer of patients from his list to theirs. But meanwhile some patients may have been seriously damaged, and from the first it was recognized that additional means would have to be provided to secure that insured patients should receive proper treatment. For the great majority of insurance doctors such means are not needed, their professional conscience is sufficiently developed to keep them up to the mark. But among over 16,000 doctors it would be unsafe to assume that all may be relied upon to give unfailing attention, and it was generally agreed that it would be necessary to adopt some method for enabling insured patients to bring forward their grievances for adjudication. At the inception of the scheme there were doctors who considered that grievances should be heard in law courts, but by most this was regarded as undesirable. Legal proceedings are expensive, a doctor who has successfully contested an unfounded complaint may be unable to obtain costs from the complainant, and the publicity of a legal action does no good to a doctor's practice. It was therefore agreed to

*An insurance doctor's obligation in this respect is expressed in his agreement with the Insurance Committee in the following terms: "The treatment which a practitioner is required to give to his patients comprises all proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess. Treatment in respect of a confinement is however expressly excluded."

†McCleary G F—Medical Officer of Health Battersea, Hampstead Bedfordshire. For record and address of author see "This Week's Issue" page 432.

‡Except a doctor who has been removed from the panel by the Minister of Health. Removal is a rare event.

set up in each area a special committee to deal with grievances.

THE GRIEVANCE COMMITTEE

Each Insurance Committee appoints a Medical Service Sub-Committee specially constituted to hear complaints against insurance doctors. The Sub Committee consists of an equal number not less than three or more than five, of local medical practitioners and of representatives of insured persons, with a neutral chairman. The Sub Committee's function is to investigate the complaint, find the facts and report them to the Insurance Committee, who on the facts so found (which, if no appeal is made, must be accepted as conclusive) decide what action should be taken. Either party may appeal against the decision to the Minister of Health.

The procedure for dealing with grievances will be more readily apprehended if we take an imaginary case and follow it through its various stages. It is similar to cases that have actually occurred.

THE CASE OF JAMES THOMPSON

James Thompson, who is twenty six years of age, is an insured person and is employed in an iron foundry at a weekly wage of \$15. Two years ago he chose Dr. Smith as his insurance doctor and was on his list when the case began. It began when Mr. Thompson awoke about two o'clock one morning with severe abdominal pain which Mrs. Thompson vainly attempted to relieve with hot applications. Mr. Thompson was reluctant to send for Dr. Smith, who lived about half a mile away, but after enduring the pain for an hour he felt so ill that he asked his brother, a boy of fifteen who lived in the same house, to go to Dr. Smith and ask him to call as soon as possible. The boy arrived at Dr. Smith's house at 3.15 A.M., rang the night bell and in answer to the doctor's inquiry through the speaking tube said that his brother had been awakened with a "terrible pain in his stomach," and that he felt very ill indeed and wanted the doctor to come round at once. He added that he had brought his brother's medical card with him to show that he was one of the doctor's insured patients. On being asked whether the patient had been sick or had diarrhoea he said he did not know, but he was sure that his brother was "terribly ill". The doctor came downstairs, and made up a bottle of medicine, which he gave to the boy, saying that the patient should take a dose at once and another every two hours if still in pain and that he would call after break fast. Mr. Thompson was greatly disappointed at not seeing the doctor, but he took the medicine, which, since it contained a substantial quantity of opium, relieved the pain considerably. About 11.45 A.M. the doctor called, found that

Mr. Thompson was suffering from acute appendicitis and advised immediate removal to the local hospital, where an operation was at once performed by a surgeon on the hospital staff, the case being urgent.

Mr. Thompson made but a slow recovery, which he attributed to the failure of Dr. Smith to visit him when requested and the consequent delay before the operation could be performed. On leaving the hospital he removed his name from Dr. Smith's list to that of another doctor, and lodged a complaint against Dr. Smith with the Insurance Committee. A copy of the complaint was sent to Dr. Smith and the case referred to the Medical Service Sub Committee.

The Sub Committee may dispense with a hearing if they deem the complaint frivolous, in this case they decided that a hearing was necessary, and Dr. Smith and Mr. Thompson were asked to attend their next meeting. At this meeting which like all meetings of the Sub Committee, was held in private, neither party being allowed to be represented by a lawyer or other paid advocate, Mr. Thompson, who had received a copy of Dr. Smith's answer to his complaint, gave his account of his illness and his brother told what happened when he called on Dr. Smith. The facts so stated were not disputed by Dr. Smith, except that according to his recollection he was called at 4.30 A.M. and not at 3.15 A.M. He said that the messenger's account of the patient's symptoms led him to think that the case was one of ordinary colic, that it was a most inclement night and that he had a bad cold and was tired out by a hard day's work. When asked why if he felt unable to go out he did not arrange for a deputy to take the call he said that the idea did not occur to him. He did not think his short delay in visiting the patient had materially affected the progress of the case. He was closely questioned by the doctors on the Sub Committee, who seemed less impressed than their lay colleagues by the reasons he gave for his failure to visit the patient when requested.

After hearing the evidence the Sub-Committee prepared a report to the Insurance Committee, in which they found the facts as stated above, inferred from them that Dr. Smith had failed to render proper service to his patient, and recommended that a sum of twenty pounds (\$100) should be withheld from his remuneration. The Insurance Committee adopted the report without discussion and sent a copy to the Minister of Health.

DR. SMITH'S APPEAL

Dr. Smith exercised his right to appeal to the Minister of Health against the decision of the Insurance Committee on the report of their

*The Sub-Committee's findings of fact must be accepted by the Insurance Committee as conclusive.

Medical Service Sub-Committee. He thought the decision was unwarranted by the facts of the case. In accordance with the regulations governing these cases, the Minister appointed an appeal tribunal consisting of three members: a medical officer and a legal officer of the Ministry of Health, and a medical practitioner selected from a panel of insurance doctors nominated by the British Medical Association. At the appeal both Dr. Smith and the Insurance Committee were represented by competent lawyers, and the witnesses, who gave evidence on oath, were subjected to searching cross-examination. The case concluded, the tribunal drew up a report to the Minister in which they stated that they saw no reason to dissent from the decision of the Insurance Committee.

The Regulations provide that in any case in which an insurance doctor has been found by the Insurance Committee (or by the appeal tribunal in a case in which an appeal has been made) to have been negligent in his treatment of the patient, the Minister shall, before arriving at a decision on the case, refer it to an Advisory Committee, consisting of the Chief Medical Officer of the Ministry of Health, two other medical officers of the Ministry, and three doctors selected from the panel of insurance doctors nominated by the British Medical Association to which reference has already been made, and shall consider their report on the case. Our imaginary case, which we have now traced to its final stage, would be so referred, and from what has happened in similar cases that have actually occurred it is unlikely that the decision of the Medical Service Sub-Committee would be modified.

THE WITHHOLDING OF REMUNERATION

It will be noted that in this case the Insurance Committee, adopting the report of their Medical Service Sub-Committee, recommended, with the concurrence of the appeal tribunal, that a sum of twenty pounds should be withheld from Dr. Smith's remuneration. In a case in which money is withheld, the Minister deducts the sum from the moneys paid by him to the Insurance Committee for providing medical services, and the Committee deducts that sum from the next payment made to the doctor. During 1933, remuneration was withheld from eight insurance doctors who had been negligent in the treatment of their insured patients.

REMOVAL FROM THE PANEL

The most severe action that can be taken against an insurance doctor under the disciplinary procedure of the health insurance scheme

is removal from the Medical List, or "panel" as it is colloquially termed. This action may be taken by the Minister of Health if he is satisfied that the doctor's continuance on the panel would be "prejudicial to the efficiency of the medical service of the insured." A case of removal usually originates in a representation made by an Insurance Committee to the Minister of Health that the continuance of a certain doctor on the panel would be prejudicial to the medical service, and on receiving such a representation the Minister must appoint an Inquiry Committee consisting of a lawyer (barrister or solicitor) in actual practice and two doctors. The Committee hear the allegations made against the doctor and his reply, the witnesses give evidence on oath, and the parties are legally represented. The Committee do not decide the question of removing the doctor from the panel; their business is to report to the Minister, stating the facts that appear to them to be established by the evidence and the inferences of fact which, in their opinion, may properly be drawn from the facts so established. The decision to remove or not to remove a doctor from the panel rests with the Minister, but before deciding he must refer the Inquiry Committee's report to the Advisory Committee mentioned above and must take their recommendations into consideration.

Very few doctors have been removed from the panel. In 1933 there was no case in which the question of removal was raised.

Complaints against insurance pharmacists are dealt with by a similar procedure, the complaints being heard by committees on which pharmacists are represented. There is, however, no advisory committee to deal with cases in which pharmacists are concerned.

It will be noted that in the procedure of the English health insurance scheme for the settlement of grievances the medical profession takes a highly important part. At every stage in the proceedings the medical aspects of the case are adequately brought to the consideration of the authorities responsible for decisions, and the medical members of the various tribunals are nearly all insurance practitioners familiar with the conditions of insurance practice. The procedure was not devised by the Government and imposed on the doctors; it is the result of many conferences between the Government and the accredited representatives of the medical profession. It has been modified from time to time, chiefly by increasing the disciplinary responsibilities of the profession, and after twenty-two years' experience it is generally regarded as an equitable, effective, and satisfactory method of dealing with grievances.

PARALYTIC TREATMENT OTHER THAN RESPIRATORY

The Important Rules in the After Care of Poliomyelitis

BY ARTHUR T. LEGG, M.D.*

THE after-care of poliomyelitis cases should start as soon as the paralysis or weakness takes place

(a) To prevent deformity (contractures)

- 1 By posterior wire splints for the legs to hold them in the normal position
- 2 By a corset to hold the trunk in normal position
- 3 By a platform splint to hold the arm in abduction to prevent any strain on a weakened deltoid
- (a') The elbow may be flexed or extended, depending on the power in the biceps or triceps
- (a'') A hand splint to prevent deformity of the hand

(b) To relieve sensitiveness

- 1 By hot packs, two or three a day
- 2 By complete rest.

No massage or manipulation should be allowed during the sensitive stage.

A complete muscle examination should be made as soon as the sensitiveness is over

Muscle training should now be started to strengthen the weakened muscles by carrying on their function voluntarily. This should be increased gradually.

Muscle training should be carried out only by a worker with a thorough knowledge of functional anatomy. The muscle training should be preceded by baking and massage to increase the circulation in the part.

Ultraviolet light therapy may perhaps be of value in improving the general condition of the patient but it should be understood that it does not constitute treatment of the paralysis.

It is better to obtain a voluntary contraction of a weakened muscle than a response to electrical stimulation. A muscle which shows a definite motor response to electrical stimulation can in most cases produce voluntary motion if placed in a suitable position. The dangers of stimulation are not only from overfatigue of the muscle without reeducation of the nerve

pathways but also from the fact that stimulation, strong enough to produce a response from muscles too weak to respond well voluntarily, is likely to spread to other and stronger muscles. In any case, electrical stimulation should never be used as a substitute for muscle training, or by any person who is not familiar with the exact location of the muscles and the degree of paralysis existing in the various groups.

Overfatigue of the weakened muscles should be carefully guarded against.

Patients should never be allowed to stand in a deformed position.

When the patient with weakened legs or trunk is standing, splints should be applied to hold the feet and knees in their normal position and a corset or jacket to hold the trunk in its normal position in order to prevent deformity.

Patients should not be encouraged to walk soon after the onset or to use mechanical exercisers.

Swimming does not take the place of localized muscle training.

Treatment in water has no more specific value than table treatment, but it is a pleasant way of doing exercises. The buoyancy of the water allows weak muscles to perform their function more easily than is possible otherwise.

The respirator has a place in the after treatment of poliomyelitis with those patients whose muscles of respiration have been weakened. In the early stages it can be used to rest the muscles of respiration, and later it can be used to increase chest expansion.

Frequent muscle examinations should be made of poliomyelitis cases, in order to record the gain or loss of power of the different muscles and the exercises should be changed accordingly.

While the most rapid regain in muscle power will take place during the first year, muscles will continue to gain power indefinitely if muscle training is continued.

All cases should be followed carefully for years to note any imbalance of muscle power which will produce deformity.

MEDICAL PROGRESS

PROGRESS IN THE SURGERY OF THE AUTONOMIC
NERVOUS SYSTEM IN 1933 AND 1934*

BY JAMES C WHITE, M D †

THIS review of progress in the field of the autonomic nervous system covers the years 1933 and 1934. Neurology is necessarily a complex subject and that part of it which deals with visceral innervation cannot be simplified beyond a certain point. An attempt has been made, however, to describe the work in as simple terms as are consistent with scientific accuracy. All angles of the subject have been considered relevant, provided they have a definite clinical bearing. For this reason the recent contributions of the physiologists are reviewed in some detail, as they have contributed so much to an intelligent understanding of these problems. The most recent fields opened to the neurosurgeon are the carotid sinus syndrome and the control of hypertension. The application of sympathetic neurosurgery to these conditions is therefore summarized at some length, as are its effects on the peripheral circulation and the ever-important rôle of the viscerosensory nerves in intractable pain.

I PHYSIOLOGY

Chemical Mediation of Autonomic Nerve Impulses

As far back as 1921 Otto Loewi discovered, on stimulating the vagus nerve of a frog that a chemical substance appeared in the heart's blood which, when perfused through the heart of a second frog, duplicated the cardiac inhibiting effects of vagus stimulation. The full development of this epochal experiment has been worked out in the last two years and has shown that stimulation of smooth muscle is carried out not by direct nervous discharge, but by a chemical mediator secreted at the nerve endings. An excellent review of the growth of this fundamental concept in neurophysiology has been written by Cannon¹, who has himself been one of the leading contributors to the development of this field. From the anatomical point of view, Stohr states that only one smooth muscle cell in a hundred is supplied with a nerve ending. The knowledge that a chemical mediator is set free in the occasional cells having nerve endings obviates the necessity for an individual neurone to each contractile fibre. These mediators have been named "parasympathin" and "sympathin." Parasympathin has been found to resemble acetylcholine and, as it is rapidly destroyed by blood or tissue esterase, its physiological effects are limited to a localized area. During nerve stimulation this substance has been found in the blood

from the heart, the sweat² and salivary glands³, and the gastric veins⁴. Dale has aptly designated these nerve endings as cholinergic, and Feldberg and his co-workers in Dale's laboratory have discovered the surprising fact that parasympathin is secreted not only at the synapse between the sympathetic pre- and post-ganglionic neurones in the paravertebral ganglia^{5, 6}, but also in the adrenal medullas⁷.

The adrenergic substance, "sympathin," which was discovered by Cannon and his co-workers¹, is liberated at all the sympathetic nerve endings on smooth muscle. This hormone, which resembles adrenalin in many ways, has never been isolated. Cannon and Rosenbluth⁸ have shown that it exists in two forms. Sympathin E, which is given off by smooth muscle when excited to contract by sympathetic impulses, is carried by the bloodstream and is capable of causing contraction in distant smooth muscle organs. Sympathin I, on the other hand, affects smooth muscle organs which relax. In character with the generalized diffuse discharge of the sympathetic nervous system, and in contrast to parasympathin, sympathin is widely distributed by the blood stream. Like adrenalin, sympathin causes contraction of smooth muscle even after complete denervation. This has been shown by Freeman, Smithwick, and White⁹ to be of real clinical importance, since even after sympathectomy, denervated organs such as the arteries are exceedingly susceptible to these chemical mediators (see below).

Autonomic Centres in the Brain

With the advance in our knowledge of neurophysiology the governing centers of the involuntary nervous system have been followed steadily upwards from the medulla oblongata through the diencephalon and have at last reached the cerebral cortex in the premotor region. Much of this work has been carried out in Dr. Fulton's laboratory at Yale, where an intensive investigation has been made on this portion of the brain. He and his colleagues have shown that stimulation of the premotor area in monkeys and chimpanzees gives rise to vigorous peristaltic movements of the gut and that bilateral extirpation causes morbid hunger and even at times obstructive intussusceptions^{10, 11, 12}. Considerable disagreement still exists concerning the control of body temperature by the cerebral cortex. Kennard¹³ claims that ablation of the premotor area in the monkey causes a failure of reflex vasodilation on the opposite side of the body, whereas Pinkston, Bard and Rioch¹⁴ have observed chronic vasodilation after removal of the neonallum. After removing a cor-

†White, James C—Assistant Professor of Surgery, Harvard University Medical School. For record and address of author see *This Week's Issue*, page 432.

responding area in a case of brain tumor, Zolinger and Schnitker¹⁵ were unable to detect any change in skin temperature of the extremities.

Investigation of the autonomic centres in the hypothalamus has been carried on by Ranson, Kabat, and Magoun¹⁶. They have contributed additional evidence that the area behind the optic chiasm contains important sympathetic centres, and that stimulation of the preoptic region causes a slowing of the heart and a fall in blood pressure, as well as contraction of the bladder (i.e., a parasympathetic discharge). Davis¹⁷ has emphasized the importance of that portion of the hypothalamus above the stalk of the pituitary (the tuber cinereum) in the control of carbohydrate metabolism.

The Cerebral Circulation

The problem of the vasomotor control of the circulation through the brain has been extensively investigated by Cobb and his co-workers during the past six years. Accurate measurement of the calibre of the pial vessels has been made possible by Forbes's brain window technique. A summary of this work has been published by Cobb¹⁸. Anatomists have long taught that the cerebral arteries do not anastomose, i.e., that they are all "end arteries". It has also been held that these arteries have no vasomotor mechanism. Recent investigations in the department of neuropathology at the Harvard Medical School have shown that both of these concepts must be revised. The pial, as well as the dural arteries show well marked constriction when the cervical sympathetic chain is stimulated or on direct application of adrenalin. The vasodilator pathway of the cerebral vessels has been found to leave the brain stem in the facial nerve, to traverse the geniculate ganglion, and thence to follow the cerebral vessels. Drugs such as alcohol, histamine, amyl nitrite and acetylcholine increase cerebral circulation, but the most effective stimulant is the inhalation of a mixture of 10 per cent carbon dioxide in 90 per cent oxygen. Clinically it is now realized that vascular spasm plays an extremely important role in syncope, migraine, and epileptic convulsions.

The Vasodilator Nerves

Rosenbluth and Cannon¹⁹ have pointed out that active vasodilator reflexes persist in totally sympathetomized animals. These investigators suggest that the vasodilator system is probably constituted and distributed as follows: A, autonomic dilators, (1) sympathetic, distributed primarily to skeletal muscle, (2) parasympathetic, distributed to special localized regions (e.g., chorda tympani nervi erigentes), B, dorsal root dilators, distributed primarily to skin and viscera, as described long ago by Bayliss. Bishop, Heinbecker, and O'Leary²⁰ have investigated this last group with the cathode ray oscillo-

graph and by means of differential blocking of the sensory and motor fibres with narcotic drugs and by pressure. They conclude that there is a special type of non-myelinated neurone in the dorsal roots and in purely sensory nerves, such as the saphenous, with cells of origin in the dorsal root ganglia. These resemble autonomic neurones and are the only fibres in the sensory root which on stimulation produce a vasodilator response. This work eliminates the somewhat clumsy explanation of "antidromic conduction" of vascular impulses by the posterior roots.

Carotid Sinus Mechanism

C Heymans and his collaborators²¹ in Ghent have made an exhaustive study of the hitherto unappreciated rôle of the carotid sinns in the regulation of blood pressure and of a large number of important visceral mechanisms. They have shown that there is a special sensory innervation situated at the bifurcation of the common carotid arteries. Impulses set up in a group of sensory end organs in the arterial wall are conducted to the brain stem by the glossopharyngeal and vagus nerves, thence they are distributed over the entire autonomic system. By this reflex mechanism a local rise or fall of blood pressure in the carotid sinus gives rise to a generalized vasodilator or vasoconstrictor response. Resection of the carotid sinns nerves in the dog results in a persistent tachycardia and a hypertension of 200 to 300 mm. After total sympathectomy this is abolished²². Certain carotid sinns reflexes, however, are only abolished by cutting the spinal cord in the upper thoracic region. The sinns are also sensitive to changes in carbon dioxide and oxygen tension, to variations in hydrogen ion concentration, and to numerous drugs.

The Reaction of the Sympathetic Nervous System in Shock

In relation to the homeostatic activity of the sympathetic nervous system it has long been appreciated that after severe accidents and operations, as well as in acute illness, this division of the nervous system does its utmost to preserve the constancy of the "milieu intérieur". Freeman²³, however has shown that after prolonged hyperactivity even this most foolproof of automatic regulating devices may go wrong and lead to the destruction of the organism which it is commonly supposed to preserve. Thus in severe traumatic shock or dehydration²⁴, medulladrenal activity causes such an intense degree of vasoconstriction that the tissues may become asphyxiated and the vital blood volume reduced to a fatal level by leakage of the plasma through the anoxic capillary walls. The stranded red blood corpuscles increase viscosity and the effective blood volume is further reduced by peripheral stagnation.

II OPERATIVE METHODS

Recent Modifications in the Technique of Cervicothoracic Ganglionectomy

The posterior longitudinal incision devised by Adson for reaching the inferior cervical and first two thoracic ganglia by resecting the central ends of the first or second ribs often results in separation or delayed healing of the wound. This is due to the necessity for continuous and forceful retraction of the tissues and also to the difficulty in suturing the incision at the edge of the spinous processes. Adson²⁵ has recognized the shortcomings of this incision and has modified it to the extent of cutting off the tips of the spinous processes. When this is done the fascia and muscle can be sutured as in a laminectomy incision. In every other respect the exposure of the ribs is unchanged.

White, Smithwick, Allen and Mixer²⁶ have advocated an oblique muscle splitting incision. This is carried from the prominent spine of the seventh cervical vertebra to the angle of the scapula. The trapezius muscle is split in the plane of its fibres and the space between the superior rhomboid and the levator anguli scapulae entered. On separating the thin fibres of the serratus posterior superior muscle, the first and second ribs are found to lie directly in the long axis of the incision. By this route less bleeding is encountered, a minimum of retraction is necessary, and an excellent exposure is obtained. This incision is particularly applicable to a unilateral approach, if a bilateral ganglionectomy is indicated, these writers feel that it is best carried out in two stages a week to ten days apart.

Gask and Ross²⁷, who prefer the anterior cervical approach, have found that it is possible to resect the chain to the second thoracic ganglion, provided the scalenus anticus muscle is transected. With this valuable modification the resection of an adequate number of ganglia is no longer a difficult procedure.

Reichert²⁸ has advocated the injection of alcohol instead of the resection of the lumbar ganglia in certain cases of intermittent claudication or threatened gangrene. He feels that it is less dangerous than operation for the elderly arteriosclerotic, and that it is better for economic reasons in many cases with thromboangitis obliterans. He reports that twenty-four out of twenty-nine of the arteriosclerotics were improved, some markedly. There was an increase in walking ability from double the former distance up to two miles. The results in the cases with Buerger's disease are less impressive.

Craig²⁹ has developed a practical posterior infradiaphragmatic approach to the splanchnic nerves. Although this has given disappointing results in hypertension, it should be of definite value in the control of pain from the upper abdominal viscera.

III EFFECTS OF SYMPATHECTOMY ON THE CIRCULATION

Coller and Maddock^{30, 31} have brought out the importance of the regulation of blood flow through the skin of the arms and legs in the control of body temperature. In the first place these areas, which on account of their irregular shape make up an extraordinarily large proportion of the total surface (i.e., 65 per cent), have a much greater function in the dissipation of body heat than does the skin of the head and trunk. Interrupting the normal heat regulating process by sympathetic ganglionectomy results in a considerable increase in blood flow to the extremities.

In a recent and most interesting review of their ideas on Raynaud's disease, Lewis and Pickering³² point out that this eponym should be abandoned, as it has come to include a number of entirely unrelated conditions. Such a grouping cannot fail to obstruct inquiry into the causation of the various maladies which are included under it. They have subdivided these into a practical and more exact classification.

- "1 Intermittent spasm of digital arteries, without complications
- "2 Intermittent spasm of digital arteries with local nutritional changes
- "3 Intermittent spasm of digital arteries with generalized scleroderma
- "4 Raynaud's phenomenon arising out of local injury, including the use of vibrating tools
- "5 Bilateral gangrene of digits in the young, and with infection, this condition is regarded as probably the result of thrombotic closure of vessels
- "6 Bilateral gangrene with haemoglobinuria from cold, a condition having probably a unique pathogeny
- "7 Bilateral gangrene of digits in the elderly, in which closure is shown to be thrombotic, but preceded by disease of the small arteries
- "8 Thromboangitis obliterans associated with Raynaud's phenomenon
- "9 Cervical rib or crutch pressure causing Raynaud's phenomenon or gangrene, so it is thought, by thrombotic and embolic processes"

Lewis and Pickering insist that gangrene cannot take place from uncomplicated vasospasm, and that in all these conditions except the first there is definite pathology in the arteries.

Surgeons who treat this group of diseases are at present considerably less enthusiastic about the results of sympathetic ganglionectomy in restoring a satisfactory circulation to the arm than to the leg. Thus Sheehan³³ states that "cervico-dorsal ganglionectomy for Raynaud's disease, although resulting in a definite improvement in the condition of the upper limb, rarely gives a complete recovery. This incomplete result, in

marked contrast to that of the lower extremity, has been noted by many surgeons." To account for this discrepancy, it should be pointed out that the leg cases usually fall in Lewis's first group. The toes very rarely go on to spontaneous gangrene and therefore the condition is more probably one of pure vasospasm. In addition, it is a simpler technical procedure to ensure cutting all the vasoconstrictor fibres to the lower extremity. However, even in the early uncomplicated forms of the disease and after complete sympathetic paralysis of the upper extremities, recurrent vasospasm is not a rare occurrence. Fitting in with an observation which has been reviewed above that denervated smooth muscle remains sensitive to adrenalin, Smithwick, Freeman and White²⁴ have found that the completely denervated arm becomes intensely sensitive to the circulating hormone of the adrenal medulla. This sensitivity is much more marked in the arm than in the leg and probably is the cause of the fundamental difference between the results of the two operations. It is a most striking phenomenon in the rabbit's ear, but disappears and permits constant vaso-dilation if the adrenal glands are inactivated.²⁵

In searching for the etiology of vasospastic disease, Craig and Kernohan²⁶ have examined the ganglia from 208 cases. In comparing their histological observations on sympathetic ganglia removed at operation with those from postmortem subjects without arterial disease, nothing was found to explain the various vascular disturbances. All the changes which have been commented on by other writers were found to be within normal limits and most of them explained on the basis of advancing age.

During the past two years gangliectomy has been enthusiastically advocated for the treatment of the cold, cyanotic legs after polio myelitis (Telford and Stopford²⁷), for the vasospastic group of patients with thromboangitis obliterans (Adson²⁸, Dier²⁹), and for extreme degrees of hyperhidrosis (Leriche and Arnulf³⁰).

One of the latest developments in the field of sympathetic neurosurgery is the treatment of hypertension. Exclusion of the periodic crises of hypertension caused by chromaffin cell tumors arising from the adrenal medulla the only type which has responded to operations on the sympathetic nervous system is the essential form which occurs among comparatively young individuals, is progressive in spite of medical treatment, and carries a uniformly unfavorable prognosis. This has been designated as the malignant type. According to Hines and Brown³¹, patients with this variety of the disease show an unusual rise in blood pressure on exposure to cold.

A number of operations have been recommended to reduce hypertension, either by eliminating vasoconstrictor tone from large areas of the body or by reducing adrenal secretion. With

the latter end in view, Do Courcy³² has recommended subtotal bilateral adrenalectomy. Although he has reported apparently good results in a series of eight cases, the observations date over too short a period to be at all convincing. The risks of the procedure and its lack of sound physiological background make it necessary to postpone final judgment as to its value. In the attempt to reduce vasoconstrictor tone, the first operative procedures consisted in sympathetic denervation of the upper and lower extremities. This did not affect a sufficient portion of the arteriolar bed to modify the systemic blood pressure. Craig and Brown³³ later advocated resection of the splanchnic nerves as they enter the abdominal cavity between the crura of the diaphragm, but the results were still unsatisfactory in the more advanced cases. The most logical procedure, but at the same time the most radical, is the section of the lower six thoracic and upper two lumbar anterior spinal roots as proposed by Adson and Brown³⁴. This operation not only eliminates all vasoconstrictor impulses to the lower half of the body, but denervates the adrenal glands and reduces intra-abdominal pressure as well. While its early results as reported from the Mayo Clinic and also by Page and Heuer³⁵ are distinctly encouraging, this radical type of operation should still be regarded as in the experimental stage, only time and a large number of cases can tell whether this new form of neurosurgery can achieve another victory over a disease which has heretofore resisted all other forms of treatment.

While underactivity of the carotid sinus causes hypertension in the dog, failure of this control mechanism does not seem to be a cause of this condition in man. Weiss and Baker³⁶ have described the interesting syndrome which is due to an hyperactive sinus. Studies have been conducted on fifteen such cases. The patients complained of dizziness and fainting attacks occurring whenever the region of the carotid bifurcation was pressed upon. In four cases these symptoms were induced merely by a sharp turning of the head, in the others they could be elicited by digital pressure. Evidence is presented that these symptoms and signs are due to stimulation of the sinus and the intercarotid nerves, not to direct vagal irritation. Three main types of cardiovascular response were observed: (a) marked asystole or slowing of the heart rate, (b) marked fall in blood pressure, (c) changes in cerebral circulation without essential slowing of the heart or fall in blood pressure. The first response is evidently due to a vagal reflex and is abolished by atropine. If the intercarotid nerves are infiltrated with novocaine, all the reflex phenomena are obliterated. In one case reported in this paper, and in a considerable number since section of the carotid sinus nerves has successfully relieved the symptoms.

IV VISCERAL PAIN

The neurophysiology of visceral pain has been greatly clarified by Heinbecker, Bishop and O'Leary's⁴⁶ demonstration that the sympathetic trunks are traversed by myelinated neurons whose histological appearance and electrical conduction properties are exactly similar to those of the peripheral sensory nerves. These neurones run through the paravertebral chain of ganglia to the posterior spinal roots, where their nerve cells are situated. The viscerosensory fibres should therefore not be considered as a part of the sympathetic nervous system, but as belonging to the somatic cerebrospinal nerves. B Cannon⁴⁷ has implanted shielded electrodes on the larger autonomic nerves of the cat and studied these animals after complete recovery. He has found the cervical and lower lumbar sympathetic chains, as well as the vagus below its recurrent laryngeal branch, to be devoid of pain sensation. On the other hand, the upper lumbar chains and the splanchnic nerves have a high degree of sensory acuity.

The Moores⁴⁸ have made a careful analysis of arterial pain. They have concluded that there is a large group of afferent neurones subserving painful sensation which end in close association with the smaller arterial branchings. These can be stimulated under experimental conditions by the intraarterial injection of irritants, such as sodium iodide and lactic acid. Under natural conditions it is probable that they function by virtue of sensitiveness to a chemical stimulus. The most common cause of arterial pain is ischemia, and under these circumstances lactic acid is probably the actual stimulating agent. Moore and Singleton⁴⁹ have shown that in the case of the viscera, arterial pain is definitely conducted along sensory neurones in the splanchnic and other sympathetic trunks. Further evidence that afferent fibres run in these channels has been added by Sheehan⁵⁰, who has shown by experimental work that the myelinated neurones of the Pacinian bodies in the mesentery travel along the splanchnic nerves. In the extremities, however, arterial pain is not affected by sympathectomy, but is abolished by section of the peripheral nerves.

Migraine

Sympathectomy appears to be of definite, if inconstant, value in the relief of migraine. Adson⁵¹ reports the cure of a case after superior cervical ganglionectomy, ligation and section of the external carotid artery, and interruption of the sympathetic connections of the internal carotid by stripping the common carotid artery. Penfield⁵² states that superior cervical sympathectomy and stripping the carotid artery gave only partial benefit in two cases of severe long-standing migraine. He then cut the ophthalmic fibres of the Gasserian root and obtained lasting complete relief. He believes that "unilateral migraine can be cured by radical neurectomy."

Atypical Neuralgias of the Head

This peculiar type of facial pain is only partly relieved by root section of the Gasserian ganglion. Reichert⁵³ reports five such cases, three of which were relieved of their residual neuralgia by alcohol injection of the upper thoracic sympathetic chain. But sympathectomy cannot be counted on to relieve these conditions, as is shown by the fact that one of Reichert's two failures has been only partially benefited by an additional superior cervical ganglionectomy plus the stripping of her carotid sheath.

Amputation Stump Neuralgias

Hamant and Bodart⁵⁴ and also Reschke⁵⁵ report four cases of severe amputation stump neuralgias. In these cases vasoconstriction was a common manifestation. Previous resections of neuromata and in one case periarterial sympathectomy had failed. These patients were relieved by resection of the regional ganglia or their rami, and have been free of pain from six months to three years.

Angina Pectoris

White, Garrey, and Atkins⁵⁶ have been able to determine the exact pathways of cardiac pain by producing it experimentally in dogs. Sutton and Lueth's method of temporarily constricting the descending branch of the left coronary artery was used. The pain was entirely interrupted by bilateral resection of the upper four thoracic sympathetic ganglia or the upper five pairs of posterior thoracic spinal roots. Resection of the lower cervical sympathetic trunks and stellate ganglia, as in the old Jonnesco operation, section of the intercostal nerves distal to the sympathetic rami, or bilateral vagotomy failed to abolish the pain. These experiments explain the frequent failures of the various modifications of cervical sympathectomy which have been recommended for the relief of angina pectoris. No cervical operation can produce a complete sensory denervation of the heart, because it leaves intact important direct connections between that organ and the upper thoracic ganglia. These thoracic ganglia should be attacked, because after their destruction the cervical sympathetic pathways are interrupted as well, since all the cardiac nerves enter the spinal cord over the upper thoracic white rami communicantes.* White⁵⁸ has shown that these experimental findings are well corroborated by clinical results in four patients in whom the upper thoracic ganglia were resected, cardiac pain on the homolateral side has been abolished. This is equally true after section of the upper five posterior thoracic roots (5 cases on record) and following successful alcohol in-

*Heinbecker⁵⁷ believes that there are also direct anatomical connections between the heart and the central nervous system over the cervical segments as well as over the fifth and tenth cranial nerves. That these pathways are of any clinical significance seems doubtful as we have had numerous experiences with cardio aortic pain referred to the head and neck, all of which have been successfully relieved by thoracic paravertebral injection.

jection of the corresponding sympathetic ramus and ganglia. The latter is undoubtedly the safest surgical procedure, but occasional failures (20 per cent) are due to its technical difficulty. Both White and Levy⁵⁹ report complete relief from angrinal attacks on the injected side in 50 per cent of cases and a very satisfactory amelioration in another 30 per cent (54 cases).

Abdominal Pain

Alvarez⁶⁰ has written an excellent discussion of this subject both from the clinical and the physiological viewpoints. In this he points out that the main sensory pathways from the upper abdominal viscera lie along the splanchnic nerves, although the sensory neurones do not, strictly speaking, belong to the sympathetic system and are no different from those in the rest of the body. In distinction from the abdominal organs, the root of the mesentery, like the rest of the parietal peritoneum, is supplied by branches of the spinal nerves. Pain from traction on the mesenteries or inflammation of the parietal peritoneum is therefore transmitted over the intercostal and lumbar nerves. Alvarez admits that there is no good explanation for the pain of peptic ulcer. Gall bladder and common duct pain has been stimulated by Zollinger⁶¹ during the course of operation by distention of these structures with a balloon. This gave rise to deep epigastric discomfort, more severe than, but similar to the attacks of indigestion in gall bladder disease. This was not relieved by infiltrating the anterior abdominal wall with novocaine. It was found impossible to produce referred pain in the back, and localized right upper quadrant pain was noted only when the gall bladder pressed on the parietal peritoneum. Scrimger⁶², who previously reported cases of ohrenre abdominal pain relieved by resection of the segmental sympathetic ramus and ganglia, has contributed two additional cases.

Pain from the Pelvic Viscera

The pathway of uterine pain has been shown to enter the spinal cord over its eleventh and twelfth thoracic segments (Cleveland⁶³). Surgically it is most accessible in the presacral region at the bifurcation of the aorta. Dohrzaniecki and Serafin⁶⁴ have published superb illustrations of dissections of this region. Adson and Massen⁶⁵ have given a very clear description of the technique for resecting the superior hypogastric plexus. Statistical evidence presented by the latter, as well as by Herrmann⁶⁶ and Wetherell⁶⁷, proves the effectiveness of this safe and non-mutilating operation in the control of functional dysmenorrhea, as well as in the type of pelvic pain which is often associated with sclerocystic degeneration of the ovaries or occasionally follows operations for chronic pelvic inflammation. Greenhill and Schmitz⁶⁸ have also emphasized the effectiveness of presacral

neurectomy in controlling the intractable pain of carcinoma of the uterus and cervix. This operation permits the surgeon to inspect the carcinomatous involvement and is so much safer than chordotomy that it should always be tried first⁶⁹, provided the malignant infiltration has not invaded the lumbosacral plexus. These surgeons have reported a remarkable series of thirteen cases, all of which experienced instant and complete relief of their suffering.

Unfortunately bladder pain is not so effectively relieved by resection of the superior hypogastric plexus. The reason for this is that part of its afferent connections run over the pelvic parasympathetic ramus to the second, third, and fourth sacral segments. Certain types of intractable cystitis can, however, be relieved by presacral neurectomy. Douglass⁷⁰ reports that in chronic interstitial and tuberculous cystitis he has been able to secure a worthwhile improvement by this operation. He believes that in the first condition cases which manifest excessive spasm of the bladder neck will respond most favorably. Learmonth and Braasch⁷¹ have advocated a similar procedure, but to date the reported results of this operation have not been very impressive.

V VISCERAL MOTOR FUNCTION

Cardiospasm

By cutting the thoracic vagi in cats, Knight⁷² has been able to produce experimental achylasia of the cardiac sphincter with dilation of the esophagus. Removal of the sympathetic fibres along the course of the celiac axis and the left gastric artery prevents the development of this condition. Clinical corroboration of this experimental observation has been put forward by Craig, Moersch, and Vinson⁷³, who report the cure of a case of cardiospasm associated with precordial pain radiating to the neck and arm. Paravertebral novocaine injection of the upper thoracic ganglia on the left side temporarily relieved the patient's pain and enabled her to swallow without difficulty. Bilateral cervicothoracic ganglionectomy has given her permanent relief.

Megacolon

The anatomy of the nerve supply of the colon and rectum has been carefully studied by Telford and Stopford⁷⁴. Their findings emphasize the fact that the sympathetic fibres which inhibit bowel tone and constrict the internal anal sphincter, can be interrupted either by resection of the lumbar ganglia by section of their ramus, or by dissecting out the plexuses around the inferior mesenteric artery and in the presacral region. This last operation is followed by loss of ejaculation and the failure of spermatozoa to pass down the tubules in the epididymis (Simeone⁷⁵) and is therefore contraindicated in

Subarachnoid injections of alcohol, as advocated by Dowdell⁷⁶, constitute an alternative method which is rapidly establishing its efficacy and safety.

male patients Very favorable reports of the clinical application of these procedures, which were originally advocated by Wade and Royle and by Rankin and Learmonth, have been reported at a joint meeting of the New York Surgical Society and the Philadelphia Academy of Surgery⁷⁶

Paralysis of the Bladder

In an attempt to localize the bladder pathways in the spinal cord, Barrington⁷⁷ has found that bladder function is uniformly crippled by lesions in the dorsal half of the lateral columns of the spinal cord Animal experimentation on the physiology of micturition by Langworthy, Reeves, and Tauber⁷⁸ has shown that the sympathetic nerves are in no way essential to normal urination, but actually inhibit this act Furthermore, their resection improves the function of the automatic bladder Essentially this parallels the observations made by Learmonth on the human being The results of the clinical application of this knowledge have been summed up by Learmonth and Braasch⁷⁹ In four cases of "cord bladder", resection of the superior hypogastric plexus brought about marked improvement in two, reduction in residual urine but a continuance of infection in the third, and failure in the fourth case Another case of neuromuscular imbalance, causing achalasia of the sphincter mechanism, was completely relieved Other cases are reported, but in these sympathectomy is combined with sphincterotomy or exploration of the cauda equina The authors are satisfied of the occasional value of this operation in their practice As time passes, no doubt indications will be more strictly defined This may mean either restriction of its field or its expansion to include other conditions

VI TUMORS

An unusually thorough analysis of the tumors which develop from the cells that wander out from the neural crest during embryonic life has been made by Lewis and Geschickter⁷⁹ This is based on 103 case records of these tumors in the Johns Hopkins Hospital The undifferentiated cell may give rise to a neuroblastoma and, as differentiation proceeds, the more adult types of paraganglioma and ganglioneuroma may develop The occurrence of all these types of tissue in the same tumor indicates a common origin

The neuroblastomas occur mainly in infants and children and have the same embryologic origin as the medulla of the suprarenal gland They are highly malignant and metastasize to the lymph nodes, liver, lung, and bones The most common symptoms are fever, abdominal mass, and anemia

The paragangliomas are the most common tumors of the sympathetic system and are encountered in the medulla of the suprarenal

gland, the carotid body, the submucosa of the appendix and small intestine, and the ganglia along the sympathetic chains They commonly occur in adults and are usually solitary and benign, but may be multiple and at times malignant Hypertension, urinary symptoms, and gastrointestinal disturbances are the most common symptoms

Ganglioneuromas usually occur in young adults and are, as a rule, benign and solitary They may occur anywhere in the central or peripheral, as well as in the sympathetic, nervous system In the latter system they are most commonly seen along the paravertebral chain of ganglia Those in the cervical region and thorax may interfere with respiration, those in the abdomen cause digestive symptoms

In contrast to the cortical tumors of the adrenal which give rise to the suprarenal genital syndrome, the sympathetic syndrome is caused by neoplasms (paragangliomas) of the chromaffin cells These have been reviewed by Collier, Field, and Durant⁸⁰ and by Belt and Powell⁸¹ The symptomatology of these tumors is quite characteristic and consists of periodic outbursts of sympathoadrenal activity, caused by an increased medulladrenal secretion The typical clinical features are paroxysmal hypertension, glycosuria, tachycardia, and vasoconstriction These are followed by flushing, nausea, vertigo, dyspnea, and susceptibility to shock or pulmonary edema When surgical removal has been successful, the patients have remained completely relieved

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL-PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C CABOT, M D

TRACY B MALLORY, M D, *Editor*

CASE 21351

PRESENTATION OF CASE

A forty-two year old Armenian salesman entered complaining of precordial pain

Five years before entry the patient developed severe occipital headache which remained almost constant for two years, increasing in severity during the day and often keeping him awake at night. Two years before entry he was seen in the Out-Patient Department where he was told that he had hypertension and advised to reduce his weight. His blood pressure at that time was 208/160. He had slight pitting edema of the ankles and hemorrhages were seen in the right retinal vessels. The urine had a specific gravity of 1.017. His headaches improved a great deal when he was on a restricted food intake. The latter, however, caused insomnia and he resumed his former voracious eating habits with the result that the headaches recurred and increased in severity. Three and a half years before admission he developed nocturia, at first two or three times a night but gradually increasing until at the time of admission he urinated every half hour during the night and every two hours during the day. There were no other urinary symptoms. Three weeks before entry he developed an upper respiratory infection associated with backache, coryza and cough. Two days later his headaches became very severe and that evening he was seized with a dull precordial pain which had persisted and was worse when he was reclining. On the evening before admission the pain was most severe. During the past three weeks he had developed marked shortness of breath, especially upon exertion. There was no edema.

His family and marital histories are non-contributory.

He had frequent colds and sore throats but there was no history of rheumatic fever or nephritis.

Physical examination showed an obese man, acutely ill and complaining of extreme headache. His breath was uremic. His respirations were labored. His pupils were regular and reacted to light and accommodation. The fundi

were slightly hyperemic and showed small hemorrhages. His chest was clear. His heart was slightly enlarged to the left, the left border of dullness being 10 centimeters from the mid-sternal line, the right 2 centimeters. No murmurs were heard. The blood pressure was 220/140. There was left costovertebral tenderness. The abdomen was obese. The liver edge was felt two fingerbreadths below the costal margin. There was no edema.

The temperature was 99.9°, the pulse 105. The respirations were 30.

Examination of the urine showed a specific gravity of 1.008 to 1.012, a large trace of albumin and a sediment which contained only an occasional red blood cell and granular cast. The blood showed a red cell count of 3,750,000, with a hemoglobin of 70 per cent. The white cell count was 10,800, 83 per cent polymorphonuclears. The stools were negative. A Hinton test was negative. The nonprotein nitrogen of the blood was 82 milligrams. A phenolsulphonephthalein test gave only 5 per cent excretion at the end of one hour. A urine concentration test showed a constant specific gravity of 1.010. The serum calcium of the blood was 8.56 milligrams and the phosphorus 6.12. A lumbar puncture gave an initial pressure of 400 which rose to 450 after combined jugular compression and which fell to 150 after removing 20 cubic centimeters. Otherwise it was not remarkable.

He was put on digitalis on the third day. He rapidly failed, became comatose, developed muscular twitchings and died on the tenth day.

DIFFERENTIAL DIAGNOSIS

DR. WALTER BAUER. It is perfectly obvious after reading the history that we are dealing with a man who had had hypertension for at least two years. We also appreciate that he had impairment of renal function. Knowing that this man was forty-two years of age and that one of his last complaints was precordial pain, one might guess that he died from chronic glomerulonephritis with an associated terminal pericarditis. It is always worthwhile to discuss this type of case because it gives us an opportunity to determine whether we can or cannot distinguish nephrosclerosis from chronic glomerulonephritis. For a long time I had thought that it was always an easy task. However, if one regularly inquires of Dr. Mallory as to his final interpretation in each individual case, one wonders if it is as easy as it would appear. When clinical deductions are based on percentage figures obtained from the analysis of a large group of cases, the differential diagnosis does not seem difficult, but in dealing with one lone case percentage figures of this sort are often of little value in arriving at the correct diagnosis. In fact, such figures may mislead one.

In going over this history I am not certain that I can make a correct diagnosis. This man first came under observation two years ago complaining of headache. At that time he was obese and had hypertension. His urine had a specific gravity of 1.017. We cannot attach too much significance to this one urine examination. When first examined, he did have retinal hemorrhages, in other words, albuminuric retinitis. If we interpret these findings as indicative of an existing nephrosclerosis, even though he had been diagnosed previously as having a benign hypertension, it is apparent that at the time of his first Out-Patient Department visit it was no longer of the benign type because an albuminuric retinitis, high diastolic pressure, etc., characterize the malignant type of hypertension. From these findings one would ordinarily say he had only a few months to live that the prognosis was serious and the outlook hopeless.

The average length of life is eighteen months. It is interesting that he should have complained of severe occipital headache for almost two years. If he really had severe headaches of two years' duration, one wonders whether he did not have hypertension prior to the time of the first entry to the Out-Patient Department. If not one might suspect that it was functional in origin. We have all seen people with hypertension of years' duration who have never complained of headache. In this particular case the headache disappeared when he went on a weight reduction diet. We do not know whether the pressure was affected. I should doubt seriously if the hypertension was influenced by dietary measures.

"Three and a half years before admission he developed nocturia." That again antedates our first knowledge of the hypertension by eighteen months. Therefore, if the nocturia is related to his final illness, it must be interpreted as meaning some impairment of kidney function eighteen months prior to the discovery of the existence of the hypertension. This symptom of nocturia became so marked that prior to the hospital entry he had nocturia every half hour during the night and every two hours during the day. This I should say was unusually frequent. Therefore, one wonders whether the recent upper respiratory infection was responsible for an associated pyelitis. This seems unlikely because he never complained of fever and had no urinary findings to substantiate such a suspicion. The recent upper respiratory infection might have caused further damage to already damaged kidneys. Nocturia of this grade explained solely on renal impairment is unusual but I suppose it can occur.

Two days before entry the headaches became very severe and he developed a dull precordial pain. There is very little more said about this pain except that it was always more marked

when he was reclining. It evidently was not sufficiently severe to require opiates. If one were to interpret the findings as those of chronic glomerulonephritis, one might suspect that the patient had a terminal pericarditis such as we do not infrequently encounter in terminal Bright's disease. From what information we have at hand I do not believe that it represented coronary heart pain.

It does state in the past history that he had frequent colds and sore throats. These infections could represent the cause of chronic glomerulonephritis, if that is what he had.

Physical examination showed him to be an obese man. I presume that in this day and age when one is confronted with an obese individual with hypertension he must always consider the possible existence of Cushing's syndrome. The existence of definite renal impairment is against such a diagnosis. However, we must appreciate the fact that some of our colleagues in New Haven have examined the pituitary glands in cases of nephritis and hypertension. I believe they have found that there are more basophilic cells in the pituitary glands of such cases than in those of normal individuals. What that proves, I do not know. I do not believe it can be interpreted to be of any etiological significance in either nephrosclerosis or glomerulonephritis. There is no further information here that would enable one to suspect the existence of a basophilic adenoma.

The man who made the physical examination evidently did not hear any pericardial friction rub. That does not rule pericarditis in or out. There is a note stating that costovertebral tenderness was present. Such a finding would be in keeping with a diagnosis of pyelitis. If present, it would help explain the frequent nocturia. However the urine examinations did not support such a diagnosis. It is surprising that the history contains no further information concerning his shortness of breath. He did have a little pitting edema on one occasion. The respirations were increased. His liver was enlarged. The lungs were reported as negative. Therefore, we cannot say that he had evidence of cardiac failure due to hypertensive heart disease. The urine examinations revealed a specific gravity of 1.009 to 1.012. The urine concentration test showed failure to concentrate above 1.010. Therefore, one must admit the existence of renal impairment if the kidneys were unable to concentrate above 1.012. The red blood cell count was 3,750,000 with a hemoglobin of 70 per cent (Tallqvist). The red blood cell count is as a rule of some significance and of help in differentiating these two types of renal lesions. We expect people with a terminal glomerulonephritis to have a more severe anemia. We look upon the anemia as of some prognostic significance. However, we do know

that occasionally a patient may enter with terminal uremia of chronic glomerulonephritis and yet have a normal red blood cell count. However, they are in the minority, in the end stages of either nephrosclerosis or chronic glomerulonephritis. You always expect to find a more severe anemia in a nephritic than in a person with nephrosclerosis. The reduction in red blood cell count and hemoglobin here could perfectly well fit with either type of case. His nonprotein nitrogen was only 82 milligrams per 100 cubic centimeters. The finding of a nonprotein nitrogen of only 82 milligrams per 100 cubic centimeters in an individual who is unable to concentrate his urine or excrete more than 5 per cent of the phenolsulphonaphthalein dye would favor a diagnosis of nephrosclerosis. We have here further evidence of impairment of kidney function as shown by a serum phosphorus of 6 milligrams per 100 cubic centimeters and a serum calcium of 8.5 milligrams per 100 cubic centimeters. This speaks for a terminal acidosis which we might see in either type of case. The lumbar puncture was negative except for increased pressure. This is of no diagnostic help. The question is of what did this man die? What is primary here? Did he have a terminal nephritis with a secondary hypertension or are we dealing with an individual who had a primary nephrosclerosis with secondary kidney impairment. Going on percentage figures, I should say that the history in this case was more in keeping with a diagnosis of nephrosclerosis than chronic glomerulonephritis. This man had no symptoms except headaches. With chronic glomerulonephritis one would expect the patient to complain of other symptoms such as weight loss, weakness, anorexia, indigestion, etc. In other words, patients with chronic Bright's disease usually have definite constitutional symptoms. This man had none. From the history alone I should be inclined to favor a diagnosis of nephrosclerosis rather than a diagnosis of chronic glomerulonephritis. I do think that the existence of nocturia for eighteen months prior to his first Out-Patient Department visit, two years before his final entry, can be used as an argument that he had some renal impairment at that time. It might be used also as an argument that he had a latent glomerulonephritis. However, I still believe that he should have had more in the way of other symptoms. I do not think that, from the laboratory side we obtain much information that enables us to make the correct diagnosis. I think the red blood cell count favors nephrosclerosis and perhaps the nonprotein nitrogen of only 82 milligrams per 100 cubic centimeters might also be used as evidence in favor of it. Therefore, I shall hazard the guess that this man had a malignant hypertension, nephrosclerosis and hypertensive heart disease

but I will not be surprised if Dr Mallory tells me the opposite. I suppose one might wonder if there is any other complicating factor here. The headache was so severe and so persistent that one must consider the possibility of some other factor. However, it seems strange that he did not have any more symptoms or signs to direct us to the cause of such a complicating factor. I think it would be safer to assume that we are dealing with an individual with one of these two conditions and not a complicating factor in addition.

DR FULLER ALBRIGHT. The service came to the same conclusion as Dr Bauer.

DR MYLES P BAKER. I remember seeing this man in the Out-Patient Department and we had the same impression as Dr Bauer, save that we considered a cerebral accident or cardiac failure a more likely eventuality. I do remember that the severe headaches were largely relieved, though the diastolic pressure was not lowered, by a little encouragement and a few suggestions that we felt at that time would not materially alter the prognosis.

CLINICAL DIAGNOSES

Hypertension, malignant
Uremia.

DR WALTER BAUER'S DIAGNOSES

Malignant hypertension
Nephrosclerosis
Hypertensive heart disease

ANATOMIC DIAGNOSES

Nephrosclerosis, malignant type
Cardiac hypertrophy, hypertensive type
Arteriosclerosis, aortic and coronary, moderate
Passive congestion—liver, spleen and kidneys
Pulmonary edema.
Obesity

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY. The autopsy on this man showed a pair of kidneys weighing 280 grams, which is only a slight degree of contraction. The capsules stripped with some difficulty and left a granular surface which was quite red in character. The granules were both fine and coarse in type. In other words the gross picture was entirely consistent with a malignant vascular nephritis. The microscopic examination entirely bears that out. There are few totally destroyed glomeruli, but the great majority show extensive hyalinization, occasionally with fresh fibrin thrombi in the capillary loops, but without proliferation of endothelial or epithelial cells. The afferent arteries of the glomeruli are extensively and uniformly involved, often with characteristic necrotizing lesions. The larger vessels show a marked

fibrous intimal thickening sometimes described as endarteritis. Also, the vessels in the other organs of the body show somewhat similar changes, very marked, as one would expect, in the spleen, but present also in the capsule of the adrenal, in the pancreas, and barely discernible in the liver. So that everything from beginning to end is entirely consistent with a malignant nephrosclerosis. I think there is little possibility of doubt in regard to the diagnosis.

The only other findings at the autopsy of significance were a considerably hypertrophied heart, as one would expect, and a moderately severe grade of coronary sclerosis. However there was no occlusion of the coronary artery, no myocardial scars and no terminal pericarditis. The lungs showed a quite severe pulmonary edema, probably an acute attack of very short duration, a rather characteristic terminal event in any type of nephritis.

DR. BAUER: I should like to ask a few questions. (1) Do you think you see an occasional case in whom you find evidence of the existence of both nephrosclerosis and chronic glomerulonephritis?

DR. MALLORY: I think one fairly often sees at autopsy a pair of extensively atrophied kidneys which microscopically show no progressive changes except in the vessels although both the clinical picture and the other autopsy findings suggest that the underlying difficulty is an old destruction of a large proportion of kidney substance by glomerulonephritis. Confirmatory evidence of the plausibility of such a hypothesis has appeared this last year in the interesting studies of Alan Moritz of Cleveland who was able to show that functionless glomeruli do not persist indefinitely as hyalinized scars as had generally been supposed in the past, but the majority disappear so completely that no scar is left at all. He showed this very prettily by glomerular counts and by special staining methods which demonstrated glomeruli in every stage of destruction.

DR. BAUER: They completely disappear.

DR. MALLORY: Yes, so that one cannot expect to find the traces of a glomerular lesion that occurred twenty years ago. The only evidence may be the tremendous reduction in the number of glomeruli.

DR. BAUER: What evidence exists to favor the view that malignant hypertension is caused by infection? How does the pathologist interpret the so-called hypertension crises?

DR. MALLORY: In answer to the first question I have a strong personal conviction that malignant hypertension is simply a very severe form of benign hypertension rather than a different disease and I doubt if it is dependent upon infection. I have to admit that occasionally pictures indistinguishable from malignant hypertension can be produced by infectious diseases such as periarteritis nodosa for instance,

but that is an entirely different syndrome that happens to involve the same structures and produce the same picture.

DR. BAUER: Certain German investigators cite cases in which streptococcus throat infections were thought to have caused the hypertension.

DR. MALLORY: Fahr in particular supports strongly the theory of an infectious origin, but I think the opinion of pathologists and clinicians the world over is very steadily shifting away from that point of view. I cannot answer the other question.

DR. BAUER: It seems to me that the theories offered in the average textbook as to the cause of the so-called hypertension crises are not based on sound physiological reasoning. We always wonder if they do not represent a true vascular episode in which the patient did not present any localized signs.

DR. CHARLES S. KUBIK: I should think our findings here would tend to confirm that view, that where cerebral symptoms appear an organic lesion has developed in the brain. Even the fact that in large numbers of these cases the symptoms are transitory, even very quickly so, does not rule out actual occlusion. I think we have material which proves that.

CASE 21852

PRESENTATION OF CASE

A thirty-four year old American painter entered complaining of swelling of the neck and groins.

About four months before entry the patient noticed a single nodular swelling about the size of a golf ball in the left groin. At the same time there developed also two small rather hard nodules under the angle of the jaw on both sides. He consulted his physician who prescribed injections of Iodex, which he used for one month without any decrease in the size or character of the glands. At the end of this period they began to increase in size rather rapidly. The ones in the neck extended to include a chain of glands on each side. The single nodule in the groin increased in size and others appeared in the right groin. He visited his physician again and this time was given potassium iodide. One month before entry he was placed on Fowler's solution 5 drops three times a day, which he took until the time of admission. There was no pain. Ten weeks before entry he began to raise phlegm which was often blood tinged and gave him a feeling of discomfort. Shortly after the onset of the glandular swelling he noticed that he was unable to hear very well. There was always a pumping noise in his head. There was some bleeding from his gums, but there was no history of change in voice, cough or hemoptysis. About three weeks

before entry he developed shortness of breath, became rather weak and tired easily.

The family and marital histories are non-contributory.

He had been a painter during the past fourteen years. He had had the usual childhood diseases. Seventeen years before entry he had influenza.

Physical examination showed a well-developed and fairly well-nourished man with marked enlargement of his neck. The glands were discrete, firm, non-tender and varied in size from 2 to 8 centimeters in diameter. There was no redness or heat of the overlying skin. The axillary, epitrochlear and inguinal glands were all enlarged up to 8 centimeters in diameter. The heart and lungs were not remarkable. The firm edge of the spleen could easily be felt upon deep inspiration. Several purpuric spots were seen on the skin near the axillae.

The temperature was 98°, the pulse 88. The respirations were 20.

Examination of the urine was negative. The blood showed a red cell count of 3,120,000, with a hemoglobin of 55 per cent. The white cell count was 4,600. The smear showed 4 per cent polymorphonuclears, 19 large lymphocytes and 62 small lymphocytes. The stools were negative. A Hinton test was negative. The basal metabolism rate was plus 37, the icteric index 20, the serum protein 6.8 per cent.

X-ray examination of the chest was negative. There were no mediastinal masses.

On the third day his temperature started to rise, reaching 106°. The white blood cell count at this time was 6,600. A smear showed 3 per cent polymorphonuclears, 21 large lymphocytes and 76 small lymphocytes. Another white cell count made the following day was 950. The smear showed cells only of the lymphoblastic type.

He rapidly failed and died five days after entry, his temperature having remained around 106° for the last three days.

DIFFERENTIAL DIAGNOSIS

DR. F. DENNETTE ADAMS. The history of fairly rapid development of nodules in the neck and groin is suggestive of some form of malignant disease, most likely lymphoblastoma of the leukemic, Hodgkin's or lymphosarcomatous type. Cancer or other tumor in the head, neck, chest or abdomen could produce metastases in the glands of the neck, possibly in the groin, but it would be unusual to have such a disease sufficiently far advanced to produce generalized adenopathy and yet manifest no local symptoms. The size and duration are against mononucleosis and other acute infections with adenopathy. Tuberculosis is possible but very improbable because of general distribution and the rapidity of growth, other

types of granulomata are equally unlikely. Bleeding from the gums is typical of the leukemias and lymphoblastomas, the blood-tinged sputum is also common. It could be caused by collection in the throat of blood which oozed from the gums overnight, by congestion or by invasion by tumor tissue farther down. Deafness, due presumably to cellular infiltration of vestibule, middle ear or auditory nerve, is not uncommon in leukemia. The pumping noise one can assume is an associated symptom. Weakness, fatigue and dyspnea would be expected in a patient with what is obviously a severe and progressive disease.

Inunction of Iodex, of course, is a useless procedure in a case of this kind. I am astonished at the frequency with which such therapeutic methods are advocated. One sees them recommended for all sorts of swellings, including tumors of the breast, and as a result valuable time is frequently lost and harm actually done. In this instance, happily, since no form of therapy would have been of permanent value, there was no actual loss. Potassium iodide was worth a trial, arsenic has its place in the treatment of leukemia. One is always on the lookout for lead poisoning in a painter. There is nothing to suggest it in this case.

History will not supply the diagnosis, laboratory tests are essential, but on the basis of history alone one would be most suspicious of lymphoblastoma or leukemia.

The type of glandular swelling described in the physical examination almost excludes tuberculosis and other granulomata but supplies no added leads.

In leukemia one would expect to find at least some enlargement of the liver and greater enlargement of the spleen, although this is not always the case. Purpuric spots, like the bleeding gums, are consistent with lymphoblastoma of the leukemic type, rare with the Hodgkin's type.

The key to the diagnosis is the blood report—the lymphocytic formula, even in the absence of a higher total leukocyte count, throws the case into the group of the lymphatic leukemias. One would be justified in assuming, I think, that earlier there was a higher total leukocyte count, and that the present figure represents depression produced by arsenic therapy or the depression so frequently seen in the terminal stages, though it is possible that the low count may have persisted throughout the disease. The red cell count and hemoglobin are consistent. The high metabolic rate is an important characteristic of the disease. It is impossible to account positively for the high icteric index. It could be due to liver damage by the arsenic, or to partial biliary obstruction by leukemic infiltration.

The rapid downward progress with high fever, marked drop in the leukocyte count, and fatal termination is typical of leukemia, par-

tecularly of the acute type. To be sure, the duration is longer than usual for the acute case which is more apt to last only a few weeks and is short for the chronic case, but there are all gradations. One can speculate as to the influence of arsenic on the leukocyte count although there are no other definite indications of arsenic poisoning (the dosage of fifteen drops of Fowler's solution daily for a month is not excessive), and also as to the possibility of terminal infection. There is no definite evidence in the record.

It seems to me that the only diagnosis which will fit the picture is lymphatic leukemia.

A PHYSICIAN You do not think the question of lead plays any part in this?

DR. ADAMS No.

A PHYSICIAN Do you think the diagnosis is consistent with the white count of 950?

DR. ADAMS Yes. The white count may drop in the terminal stages.

A PHYSICIAN How do you account for the high temperature?

DR. ADAMS Also a common terminal event.

A PHYSICIAN Is there any other condition in which you get a lymphocyte ratio so high?

DR. ADAMS Pertussis often shows a lymphocytic formula but rarely as high as this although the total count would probably be higher. Mononucleosis might give a similar blood picture.

A PHYSICIAN Do you see it very often in pertussis?

DR. ADAMS One hears about it but I do not happen to see it as I rarely see children. Do you, Dr. Mallory?

DR. MALLORY No.

A PHYSICIAN How do you account for the metabolism?

DR. ADAMS The metabolism is always high in myeloid leukemia. I do not know why. This finding is so consistent that it is used as a diagnostic factor in such cases. It may be but is not necessarily high in lymphatic leukemia.

A PHYSICIAN Do you feel that the white cell count had been this low throughout?

DR. ADAMS I believe it was probably high earlier in the disease but would prefer Dr. Mallory's opinion.

DR. MALLORY It could have been higher before or it could have been this low or lower throughout.

A PHYSICIAN Do you ordinarily get such a count with leukemia?

DR. MALLORY Not ordinarily, but I have seen cases start high and fall below normal and other cases which start at a low level and later rise to 40,000 or more.

CLINICAL DIAGNOSES

Lymphatic leukemia.
Bronchopneumonia

DR. F. DENNETTE ADAMS' DIAGNOSIS

Lymphocytic leukemia acute

ANATOMIC DIAGNOSES

Lymphohlastoma, aleukemic leukemic type
Aplastic anemia, terminal
Bronchopneumonia

PATHOLOGIC DISCUSSION

DR. MALLORY The autopsy showed generalized lymph node enlargement, a normal sized liver without any sign of leukemic infiltration and a spleen that was only moderately enlarged, 550 grams which is small for leukemia. There was a terminal pulmonary infection which was peculiar looking histologically because there was a reaction of fibrin and red cells but no leukocytes whatever. In other words, it looks like the pneumonic reaction in agranulocytosis and I think that fits his terminal condition. As I remember it, there was no differential to go with that final white cell count, but there were probably no polymorphonuclears at all.

In true leukemia you expect to find the bone marrow completely flooded with leukemic cells—so many that all other elements are displaced and you have to hunt hard for islands where the red cells, megakaryocytes and normal white cells are being formed. Instead this patient has a completely aplastic marrow in which we could not find either normal hematopoiesis or leukemic infiltration. If you gave me the sections of the bone marrow and told me nothing about the history I would call it aplastic anemia, but it is quite obvious that is not the whole diagnosis.

Microscopic sections of the lymph nodes showed a perfectly typical lymphoma and the spleen showed an infiltration consistent with leukemia. The diagnosis of aplastic anemia could not explain the lymph nodes and could not explain the spleen. A diagnosis of lymphoma in leukemic form does not explain the bone marrow. We have to make two diagnoses. There is no question that it is some form of lymphoma of which there is postmortem evidence only in the lymph nodes and spleen. It was most probably leukemic and at one time the bone marrow was involved. Then something happened—probably pretty suddenly—and knocked out all those cells in the bone marrow and produced a final picture that looks like complete aplasia of the bone marrow. The question as to what that factor was comes up. We have had one other proved leukemia in whom we did a sternal puncture two weeks before his death and found a typical leukemic infiltration with high unclassified cells. Two weeks later he died and showed a completely aplastic marrow. In the interval he developed an acute streptococcus infection for which he received no medication.

I do not know whether it was part of the leukemia per se or secondary to the streptococcus infection. In this man there is evidence of a terminal infection but apparently of only short duration—just the last day or two of his life. I do not believe that infection could have knocked out the bone marrow so completely in such a short length of time. He had received Fowler's solution for a long time which is reported sometimes to knock out the bone marrow badly. That is another possibility. He had not received any x-ray treatment.

A PHYSICIAN Is it not said that x-rays will stimulate polymorphonuclear production?

DR MALLORY I have heard that claimed. I do not feel very confident about it. I think they might sometimes but I should be more afraid of their depressing them.

DR ADAMS Considering the extent of his

bone marrow destruction one would expect the red cell count to have been lower. I suppose it might have been so recorded had further observations been made before death.

DR MALLORY He was in the hospital only five days and a good deal of the destruction of the bone marrow must have occurred in that five day period. There was only a single red cell count.

DR ADAMS Did you account for the head symptoms?

DR MALLORY We did not have permission to examine the head. However, Dr Soma Weiss of the City Hospital recently has looked up all the leukemias at the City Hospital and here at the Massachusetts General Hospital. He has found evidence of much more frequent central nervous system involvement than is generally supposed.

THERE WERE GIANTS IN THOSE DAYS

In the Educational Symposium which appeared recently in the *Journal* the history of the Massachusetts Board of Registration in Medicine was reviewed briefly, after noting some of the outstanding points in the history of the movement which led to the enactment of the statute of 1894, by which the Board was created.

We are removed from those days only forty years, according to the calendar, but from the spirit of the Victorian age, then passing off the stage by seeming aeons of difference. It is difficult for us to realize the emotional excitement of the medical controversies of the nineteenth century, and the sectarian bitterness with which some of the antagonists arrayed themselves for battle. The questions which presented opportunities for the generation of so much heat we have forgotten and when they are recalled to us

we wonder if we could ever get so excited about anything.

For thirty five years, there had been no statute controlling the practice of medicine in Massachusetts except the criminal law, and since the other states, except one, had some sort of medical practice act, for years there had been seeping into Massachusetts many of the outcasts from other states. The situation has a familiar parallel to-day.

It is impossible for us who have not lived through it to realize the strength and the character of the opposition to the medical practice act of 1894, which had to be overcome, and to the credit of the leaders of the medical profession of those days, was overcome. The names of the men who took an active part are well known to us. What we forget is the clearness of vision, and the earnestness of purpose and the dogged determination to overcome, which characterized them, of whose labors we reap the harvest.

Note the contemporary characterization of the opposition "Medical blacklegs of all kinds, deceitful clairvoyants long haired spiritualists, neoromancers, wizards, witches, seers, magnetic healers, pain charmers, big Indian and Negro doctors, abortionists, harpies who excite the fears and prey on the indiscretions of the young of both sexes, who treat venereal diseases with the utmost secrecy and dispatch, who have good facilities for providing comfortable board for females suffering from any irregularity or obstruction, who sell pills which they are particular to caution patients when pregnant against using."

There has been some progress in forty years. The opposition to progress has changed its face. To meet and overcome this opposition, there is needed to-day the same clear thinking, the same determination, the same valor, which the giants of that day possessed, and of which the tradition has become our inheritance.

THE INFANTILE PARALYSIS SITUATION IN MASSACHUSETTS

The incidence of infantile paralysis in Massachusetts is considerably larger than was expected earlier in the year. Up to August 21, the State Department of Public Health had reports of 345 cases and the expectation is warranted that by the time this statement appears there will have been reported over four hundred cases.

The important centers of the outbreak of this disease are Boston, Fall River, the North Shore and the Merrimack Valley. The western part of the State has been comparatively free from invasion thus far.

By advice of the State Department of Public Health and permission of the Editor of the

Journal of the American Medical Association an article written by Dr Arthur T Legg, which was published with others in connection with the exhibit on Poliomyelitis at the New Orleans Session of 1932, appears on page 415 of this issue

This will give approved information relating to the aftercare of patients with this disease and correct the attitude held by some. In many cases, delay in treating these patients has made a reasonable degree of recovery impossible. Expert opinion and correct physiotherapy often determine the future condition of these patients. The dictum that manipulation and massage are to be avoided during the sensitive stage should be followed. The family physician can, with advantage to his patient and himself, secure early expert advice in every doubtful case.

SCHOOL DAYS

It may be a small kindness, from the point of view of the school child, to issue a reminder in August that school days will soon be upon us. For the older person, however, who must bear some of the responsibility for this educational venture, whether parent, teacher or physician, there are certain preparations which must be borne in mind and the earlier they are looked to the better. Some two million children in the land of the free and the home of the brave will be initiated into the mysteries of academic life this fall. Before entering the public schools of many of our states they must be vaccinated. All of them should be, whether it is required or not, whether it is public or private school in which they are to be matriculated.

A lesser number, unfortunately, will have been immunized against diphtheria. Here the advice of the family physician or pediatrician will carry weight, and advice on this important subject should be given voluntarily. In other ways how well is the child physically equipped to embark upon his scholastic career? Wise parents will have ascertained beforehand if their children's hearing is unimpaired, their vision normal and their respiratory tracts unhampered by obstructing adenoids or diseased tonsils.

It is the first important step that the child is taking, away from the affectionate security of his home, he is going into the outside world at last, not as a tourist but for a purpose and he should be prepared to meet that purpose without handicap.

The teacher, the school nurse and the school physician have also their responsibilities to shoulder. Physical or mental defects in the child, hitherto unnoticed, must be recognized, and the proper machinery set in motion to correct them if they are remediable. It must be borne in mind that many children, for the first time in their lives, will be exposed to a barrage

of infectious diseases, and their first year in school will be the year when they are most susceptible to these contacts. Such exposures should be reduced to a minimum by teacher and nurse, who will remember that the common cold is an acute infection, often dangerous and highly communicable, even if it is they themselves who are harboring it!

MISCELLANY

A NATIONAL HEALTH SURVEY

The President of the United States has approved an allotment of \$3,450,000 for the employment of 3500 workers on relief rolls to operate in nineteen states to get health histories of families. The work

will be directed by the United States Public Health Service.

Special attention will be devoted to heart diseases and to illnesses due to certain occupations or income groups. The underlying purpose is to acquire information not otherwise available in hospital records and reports of other institutions for the use of research scientists and doctors.

DR. FRANCIS R. MAHONY BECOMES A MEMBER OF THE MASSACHUSETTS BOARD OF REGISTRATION IN MEDICINE

In order to meet the provision in the law that no Medical Society may have majority representation on the Massachusetts Board of Registration in Medicine Dr. Francis R. Mahony has resigned from the Massachusetts Medical Society. He was nominated by Governor Curley to fill the position made vacant by the retirement of Dr. Hovey of Springfield.

This action by Dr. Mahony calls for appropriate recognition by the Society of the sacrifice of this membership. He is now the second doctor who has given up membership in the Society in order to serve the State in this important capacity.

A PLAN TO MEET THE MEDICAL NEEDS OF LOW INCOME GROUPS

A Committee on Medical Economics of the North Side Branch of the Chicago Medical Society has studied the problem relating to meeting the medical needs of low income groups. Its first conclusion is that "The responsibility of providing that care for the indigent sick should rest with all taxpayers." The rest of the report is devoted to a plan for dealing with the group whose incomes are between \$750 and \$1,000. The attendance of many patients at the advertising clinics is deplored because such organizations have entrenched themselves in a field which should have been controlled by organized medicine. The suggested remedy is set forth as follows: "Why should the medical profession be expected to donate services and at the same time pay in taxes its share of the cost of sickness among the indigent? Remuneration for this medical service should be added to the other expenses connected with sickness among these people and the total should be carried equitably by all taxpayers."

The purpose of this plan is commendable and the experiment, if put into operation, will be watched with interest. Success will depend on the devotion and ideals of the doctors participating in the plan and the efficiency of the social service adjunct. Much of the trouble with such schemes is likely to be lack of general cooperation or dissensions among those who carry out the details, but this is no excuse for indifference on the part of the medical profession which long ago should have devoted more thought to the medical needs of the groups in the low income brackets.

A STUDY OF THE HEALTH AGENCIES OF BOSTON

In 1934 Dr Haven Emerson and Anna C Phillips made a comprehensive study of the organized care of the sick and of the health agencies of Boston for the committee on the study of the social and health agencies of the city. The report of this study has been abstracted and the findings and recommendations of so well recognized an authority as Dr Emerson are well worth careful consideration.

The problems presented to the committee primarily concerned hospitals, outpatient services, medical social service, domiciliary care and health agencies. So far as hospital beds for acute conditions and obstetrics are concerned Boston apparently has an excessive number in relation to the population needs of the city proper, however Boston's traditional provision for hospital care for patients from the Metropolitan area beyond the city limits and from residence elsewhere in Massachusetts and other New England states is probably sufficient justification for this apparent excess.

A serious inadequacy exists in the institutional provision for chronic invalids evidenced both by the lists of persons waiting their turn for admission to the existing six institutions and by the proportion of patients in the general hospitals who should be cared for in institutions for the chronically ill. Studies by the Massachusetts Department of Public Health in 1929, 1930 and 1931 also indicate that Boston lacks sufficient care for chronic disease.

Existing facilities for convalescent care are also seriously inadequate. Boston has approximately 18,440 patients annually who would benefit by convalescent care with sufficient beds at present for not over half this number.

Domiciliary medical care long handled by the Boston Dispensary, the Massachusetts Memorial Hospitals, the Medical Mission Dispensary and the Jamaica Plain Dispensary has been a bone of contention and the city has only recently recognized its responsibility in the matter.

Visiting nurse service has been provided by the Community Health Association, and it is time that the municipality recognized its responsibility for appropriate care of the dependent sick, whether the cost of care falls upon the hospitals of the city, the hospital operated by private control or upon the Community Health Association Visiting Nurses.

In social service work, additional personnel is needed in the medical social service department of the City Hospital.

It is recommended, in conclusion, that the city should make contractual agreements with the privately controlled hospitals to care for patients at times when the general medical and surgical beds

at the Boston City Hospital are occupied to normal or ninety per cent of the capacity of the hospital, that the city should provide either by an external service at the City Hospital or by contractual agreement with private organizations domiciliary care for persons eligible for free care, that a home for chronic patients be provided on the mainland, that hospitals or houses devoted to the care of convalescent patients are needed to relieve the general hospitals of the care of those patients who no longer need the costly and elaborate skill and equipment required during acute illness.

It is further recommended among other things, that the private hospitals go forward with plans at present under consideration to make possible for persons of moderate means the payment for hospital care by periodic payment on a membership basis of sums sufficient to assure them of hospital care at such time as subsequent sickness may require. Various minor institutions it is believed should discontinue their activities and various possible mergers in the interests of efficiency and economy are suggested.

THE CONTROL OF COMMUNICABLE DISEASES

In the Bulletin of the United States Public Health Service, Volume 50, Number 32, August 9, 1935, there appears the revision of previous reports covering the control of communicable diseases. This is the product of the Subcommittee on Communicable Disease Control of the Committee on Research and Standards of the American Public Health Association, and it has been approved by the United States Public Health Service.

This publication should be in the offices of all practicing physicians for it sets forth in concise form the definitions of terms employed in public health rules and regulations, a list of the diseases requiring notification to health authorities, the diagnostic etiology, source of infection, mode of transmission, incubation period, period of communicability, susceptibility and immunity, prevalence, methods of control and general measures to be observed.

When practitioners learn and apply all that is set forth in this publication the dangers incident to communicable disease will be greatly modified and physicians will be more effectively adjuncts to public health authorities.

DR. JOHN P. SUTHERLAND IS ON A MEDITERRANEAN CRUISE

On August 24 Dr John P. Sutherland sailed from New York on the SS Roma for a Mediterranean cruise.

INTERNATIONAL UNION AGAINST
TUBERCULOSIS

The Executive Committee and the Council of the International Union Against Tuberculosis, whose Secretary General is Prof Fernand Bezançon, met in Paris, at the Headquarters of the Union, 66, Boulevard St Michel, on July 10 and 11, 1935, under the chairmanship of Dr Piestrzynski, Under Secretary of State for Poland. Delegates from twenty countries attended this meeting. The administrative meeting of the Council was devoted to the preparation of the programme of the Conference of Lisbon which is due to take place on September 8, 9 and 10, 1936. The agenda of this Conference are now definitely settled and will include the three following subjects: "Radiological Aspects of the Pulmonary Hilum and Their Interpretation", opening report of Prof Lopo de Carvalho (Portugal), "Pri-

mary Tuberculosis Infection in the Adolescent and the Adult", opening report by Dr Olaf Scheel (Norway), "The Open Case of Tuberculosis in Relation to Family and Domestic Associates", opening report by Sir Henry Gauvain (Great Britain).

At the scientific meeting of the Council Prof Lyle Cummins (Cardiff) occupied the Chair. Professor Madsen, of Copenhagen, submitted a report on "Tuberculin Standardization and Tuberculin Tests". Dr Kendall Emerson, Managing Director of the National Tuberculosis Association, gave an account of the work of Dr Long and his collaborators who claim to have isolated the active principle of tuberculin. In a discussion in which Prof Madsen, Prof Lyle Cummins, M Boquet, Prof F Bezançon, Professor Sergeant, Prof Debré, Dr Lesné, Dr Rist, Dr Troisier, Dr Saenz, etc, took part, the respective merits of Pirquet's cuti-

reaction and Mantoux's intradermal test were compared. The majority of the French speakers expressed a preference for the former method while their colleagues from other countries spoke on behalf of Mantoux's test. They all agreed on the advisability of adopting a standard tuberculin and a uniform tuberculin test.

THE ILLEGAL PRACTICE OF VETERINARY MEDICINE

In a letter to Dr Begg Secretary of the Massachusetts Medical Society Dr E. W. Babson Secretary of the Board of Registration in Veterinary Medicine, has called attention to a number of complaints received by that Board that physicians have practiced one or more branches of veterinary medicine such as vaccinating dogs against rabies and dismembering treating fractures and eye troubles, and have collected fees for some of this work.

Section 59 of Chapter 112 of the General Laws of Massachusetts provides that any person who practices or attempts to practice veterinary medicine shall except as provided in section sixty-five be punished by a fine of not less than fifty dollars or imprisonment for not less than two months or both. Exemptions set forth in section 60 permit veterinary service by a person in case of an emergency and by farmers who may be serving neighbors.

No exemptions are given for physicians even in treating their own dogs, so far as the wording of the law appears in the copy submitted Dr Babson evidently does not want to have to proceed against physicians and hopes that general knowledge of the law will relieve him of this necessity.

RELIABLE APPARATUS

The *New England Journal of Medicine* has received from the American Medical Association a small pamphlet containing a list of the apparatus accepted by the Council on Physical Therapy the first one published under the direction and supervision of the Council. In addition to the list and description of accepted apparatus, the pamphlet contains indications for the use of each type and a statement relative to efficacies and dangers.

This pamphlet is a real contribution on the part of the American Medical Association in behalf of rational therapeutics and is an effort to help place physical therapy on a sound, scientific basis for the benefit of the medical profession.

One of the purposes of the Council on Physical Therapy is to protect the medical profession and thereby the public, against inefficient and possibly dangerous apparatus and against misleading and deceptive advertising in connection with the manufacture and sale of devices for physical therapy.

Apparatus Accepted includes all the devices accepted by the Council prior to May 1935. Any physician can obtain this pamphlet free by writ-

ing to the Secretary Council on Physical Therapy A. M. A., 535 North Dearborn Street, Chicago, Illinois.

MEMBERS OF THE COUNCIL

H. E. Mock, M.D. D.Sc., Associate Professor of Surgery Northwestern Medical School Chicago, *Chairman*

W. W. Cohlentz, Ph.D. Radiation Physicist, Bureau of Standards, Washington D.C.

J. S. Coulter, M.D. D.T.M. Assistant Professor of Physical Therapy Northwestern University Medical School Chicago

A. U. Desjardins, M.S., M.D. Assistant Professor of Radiology Mayo Foundation, and Director Division of Radiology Mayo Clinic, Rochester

F. J. Guenslen M.D. Professor of Orthopedic Surgery University of Wisconsin Medical School Milwaukee

W. E. Garrey Ph.D. M.D. Professor of Physiology Vanderbilt University School of Medicine Nashville
Yandell Henderson Ph.D. Professor of Physiology Yale University New Haven

Howard T. Karaner M.D., Professor of Pathology Western Reserve University School of Medicine, Cleveland

Frank H. Krusen, M.D., Associate Dean, Temple University School of Medicine Philadelphia

G. M. MacKee M.D. Professor of Dermatology and Syphilology, and Director of the Department of Dermatology and Syphilology New York Post-Graduate Medical School and Hospital New York

R. B. Osgood A.B., M.D. John B. and Buckminster Brown Professor of Orthopedic Surgery Emeritus Harvard University Medical School, Boston

Ralph Pemberton M.S. M.D. Professor of Medicine, Graduate School of Medicine University of Pennsylvania

Olin West, M.D. (Ex-Officio) Secretary and General Manager of the American Medical Association Chicago

Morris Fishbein B.S., M.D. (Ex-Officio) Editor of the *Journal of the American Medical Association* Chicago

Howard A. Carter B.S., in M.E. Secretary of the Council on Physical Therapy American Medical Association 535 North Dearborn Street, Chicago

EXTENSION EDUCATION IN PHYSICAL THERAPY

One of the aims of the Council on Physical Therapy of the American Medical Association is to promote extension education in physical therapy.

The Committee on Education of the Council believes that one of the best ways of extending post graduate instruction in physical therapy is to arrange for practical talks to be given before state, county or other medical societies. Experience, especially in New York and Pennsylvania, has shown that such programs are eagerly received by the profession.

The Council is prepared to assist medical societies by furnishing general advice as to programs and by suggesting qualified personnel

The following topics are offered as being of interest to the general practitioner

- The Present Status of Physical Therapy
- Physical Therapy in General Practice
- Body Mechanics and Posture Training
- Massage—Indications and Effects
- Pathological Conditions Helped by Physical Therapy
- Therapeutic Exercise
- Radiation Therapy
- Hydrotherapy
- Fever Therapy
- Diathermy, Medical and Surgical, Including Short Wave

Motion pictures on the following subjects are available for loan

- Massage—Technic
- Graduated Active Motion
- Occupational Therapy
- Effects of Heat and Cold on Blood Circulation
- Effects of Massage on Blood Circulation

In addition, exhibits on physical therapy can be arranged in conjunction with the Committee on Scientific Exhibit, available on request

Anyone desiring help in program planning or loans of films or exhibits is advised to write the Secretary, Council on Physical Therapy, A. M. A., 535 North Dearborn Street, Chicago, Illinois

WEIGHT REDUCER CAUSES BLINDNESS
GOVERNMENT AGAIN WARNS PUBLIC

"Blindness from the use of dinitrophenol for reducing weight has not stopped the use of the drug in spite of repeated warning," says W. G. Campbell, Chief of the Federal Food and Drug Administration.

The eye cataracts observed in dinitrophenol poisoning develop with a rapidity and malignancy hitherto unknown, and result in total blindness within a comparatively short time. This drug may

produce acute poisoning, the symptoms of which are nausea, stomach and intestinal distress, sweating, flushed skin, high fever, rapid breathing, and muscular rigor followed by death. The drug also damages the liver, kidneys, heart and sensory nerves. It produces agranulocytosis, a blood disorder also noted in cases of poisoning with amidopyrine, a common ingredient of medicines for the relief of pain.

Dinitrophenol is sold under many fanciful names, sometimes accompanied by a statement of the presence of the drug itself. Some of the names under which it has been or is now being sold are reported by the Food and Drug Administration as follows: Nitromet, Dinitrolac, Nitra-Phen, Dinitriso, Formula 281, Dinitrose, Nox-Ben Ol, Re-Du, Aldinol, Dinitrenal, Prescription No. 17, Slim, Dinitrole, Tabolin and Redusols.

RÉSUMÉ OF COMMUNICABLE DISEASES IN
MASSACHUSETTS FOR JULY, 1935

Disease	July 1935	July 1934	5 Yr. Average*
Anterior Poliomyelitis	46	20	37
Chicken Pox	379	371	357
Diphtheria	30	43	109
Dog Bite	1208	1405	866
Epidemic Cerebrospinal Meningitis	8	6	5
Gonorrhea	594	559	609
Lobar Pneumonia	163	155	113
Measles	595	775	1100
Mumps	241	207	241
Scarlet Fever	281	270	400
Syphilis	339	291	325
Tuberculosis Pulmonary	332	280	367
Tuberculosis Other Forms	29	40	51
Typhoid Fever	13	17	21
Undulant Fever	3	0	0
Whooping Cough	347	930	673

*Based on figures for the preceding five years.

RARE DISEASES

- Actinomycosis was reported from Boston, 1.
- Anterior poliomyelitis was reported from Andover, 1; Beverly, 1; Boston, 19; Cambridge, 1; Everett, 1; Fall River, 6; Haverhill, 1; Lawrence, 3; Lowell, 3; Lynn, 2; Marblehead, 1; Northampton, 1; Springfield, 1; Waltham, 2; Watertown, 1; Weymouth, 1; Worcester, 1; total, 46.
- Dysentery (amebic) was reported from Worcester, 1.
- Dysentery (bacillary) was reported from Quincy, 1.
- Encephalitis lethargica was reported from Salem, 1.
- Epidemic cerebrospinal meningitis was reported from Boston, 3; Fall River, 1; Gloucester, 1; Malden, 1; Revere, 1; Shrewsbury, 1; total, 8.
- Malaria was reported from Boston, 1.
- Pellagra was reported from Boston, 1; Salem, 1; Stoughton, 1; total, 3.

Septic sore throat was reported from Boston 2 Cambridge, 1 Dighton 1 Fall River 1 Lowell 1 Lynn, 2 Malden 1 Medford 4 Quincy 1 total 15

Tetanus was reported from Boston 1 Lynn 1 Pelham 1 Quincy, 1 total 4

Trachoma was reported from Boston 4 Fitchburg 1 New Bedford 1 Revere 1 total, 7

Trichinosis was reported from Brockton 1

Undulant fever was reported from Williamshurg 2 Worcester 1 total 3

Infantile paralysis, through July showed nothing alarming. The cases were localized in Boston Fell River and the northeastern area.

Diphtheria was reported to less than one quarter of the July 1932 figure

Typhoid fever showed its usual summer increase but compares well with last years low incidence

Pulmonary tuberculosis and lobar pneumonia showed a slight, though not remarkable increase over the previous years figures.

Tuberculosis (other forms) had its lowest reported July incidence

Scarlet fever for the second consecutive month, was reported to a higher figure than for the previous year which may mean an increased prevalence this coming fall and winter

Measles, epidemic cerebrospinal meningitis, chicken pox and mumps showed nothing remarkable.

German measles while on the decline for the year had its highest reported July morbidity

CORRESPONDENCE

AN APPEAL FOR DATA TO BE INCORPORATED IN THE DIRECTORY OF THE AMERICAN MEDICAL ASSOCIATION

American Medical Association
535 North Dearborn Street, Chicago
Directory Department

August 13 1935

Dr Alexander S Begg Secretary Massachusetts Medical Society

Dear Dr Begg

The work of revising and compiling the new Fourteenth Edition of the American Medical Directory has been started

After every Directory is published we receive a number of complaints from physicians who have not been listed as Members or Fellows of the American Medical Association. Some of these men have possibly lost appointments with industrial firms insurance companies railroads etc., because they were not indicated as members. They may have been members and let their membership lapse or new men in the community who failed to join their local society in time to indicate this information in the Directory

To eliminate such criticism, we are asking Secretaries of State Medical Societies and Editors of State Medical Journals to cooperate in notifying all

delinquents and eligible applicants that a new Directory is going to be published. It would aid greatly if a notice were placed in your publication calling to the attention of your readers the importance of sending in their data promptly when requested and the keeping up of their membership in your Society

It will probably be two years, or 1938 before our other Directory will be issued

Thanking you for your assistance in this matter we are

Very truly yours

F V CARROLL, *Manager*

OFFICIAL ACTIONS OF THE BOARD OF REGISTRATION IN MEDICINE

State House Boston

August 16 1935

Editor *New England Journal of Medicine*

This is to inform you that at a meeting of the Board of Registration in Medicine held August 15 1935 it was voted to suspend until the first of September 1935 the registration of Dr Alinsworth Isherwood of Dracut, Massachusetts for neglect in the care of a patient.

Yours very truly

STEPHEN RUSHMORE, M.D., *Secretary*

THE TREATMENT OF EPISTAXIS

August 23 1935

Editor *New England Journal of Medicine*

For several years I have found quite efficacious in cases of epistaxis a simple expedient which so far as I know has not been published in medical books or in first aid manuals

Based upon the fact that the site of most nasal hemorrhages is the forepart of the septum, it consists merely in firmly squeezing or having squeezed with the thumb and index finger of either hand the sides of the lower or flexible part of the nose as closely as possible to the upper or hard part and to the adjacent regions of the cheeks and, after several minutes gradually releasing the pressure unless the bleeding should recur

Yours truly

G W HANDE.

213 Burncoat Street,
Worcester Mass

RECENT DEATHS

JACKSON—CHARLES WILLIAM JACKSON M.D., a retired physician of Springfield, Massachusetts died at his home August 21 1935. He was born at North Brookfield in 1852 the son of Charles and Phoebe (Harwood) Jackson and was a descendant of Major Peter Harwood who served in the War of the Revolution.

Dr Jackson graduated from the University of Vermont Medical School in 1884. He joined the

tary training to the young Medical Corps Reserve Officers on the staff of that institution, who could not attend summer camps. It developed that Reservists not connected with the Clinic desired to attend. It was noted that inasmuch as the military work was given in the afternoon and evening hours, these men were able to attend the strictly professional presentations by the staff of the Mayo Clinic during the morning hours. In recent years, special professional presentations have been arranged as a regular part of the course.

The program will follow the plan which has been so successful in past years. The morning hours will be devoted entirely to professional work in special clinics and study groups. Officers in attendance may select the course they wish to follow from the wide variety of presentations offered. The afternoons and evenings will be devoted to Medico-Military subjects.

The Staff and Faculty of the Mayo Clinic will present the professional training, while the Medico-Military Program will be under the direction of the Surgeon of the Seventh Corps Area (Army) and the Surgeon of the Ninth Naval District (Navy).

Enrollment is open to all Army and Navy Reservists of Medical Departments, in good standing. Applications should be submitted to the Surgeon, Seventh Corps Area, Omaha, Nebraska, or the Surgeon, Ninth Naval District, Great Lakes, Illinois. Enrollment is limited to two hundred.

The Surgeon Generals of the Army, the Navy and the Public Health Service have all signified their desire and intention of being present during at least a portion of the course.

INTERNATIONAL MEDICAL POSTGRADUATE COURSES IN BERLIN

The Berliner Akademie für ärztliche Fortbildung, the successor of the Dozentenvereinigung für ärztliche Fortbildung in Berlin, which is managed by the Chief Burgomaster of Berlin, is holding the following medical postgraduate courses in the Autumn of 1935:

- 1 Throat, nose and ear course (30 September 12 October) Fee 120 RM
- 2 Course in infectious diseases (30 September 5 October) Fee 40 RM
- 3 Internal medicine from the point of view of functional pathology and therapy (7-19 October) Fee 60 RM
- 4 The biology of heredity and racial purity in medical practice (7-12 October) Fee 40 RM
- 5 Course in tuberculosis in the City of Berlin's Tuberculosis Hospital "Waldhaus Charlottenburg" in Sommerfeld (21-26 October) Fee 50 RM
- 6 The surgery of intrathoracic diseases with special regard to pulmonary tuberculosis (28 October 1 November) Fee 80 RM
- 7 Special courses in all branches of medicine, with practical work at the bedside and in the

laboratory, are held every month. The fee is 50.80 RM for eight periods of two hours.

For programmes and further information apply to the Geschäftsstelle der Berliner Akademie für ärztliche Fortbildung, Robert Koch Platz 7 (Kaiserin Friedrich Haus), Berlin NW 7.

Foreign doctors and German doctors resident abroad are granted a reduction of fare of 60 per cent on the German Railways Company's lines, a foreign doctor can reduce the cost of his stay considerably by utilizing what are called "registered marks", arrange matters with the local bank before starting.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, SEPTEMBER 2, 1935

Wednesday, September 4—
11-12 M. Clinico-Pathological Conference Children's Hospital

Saturday, September 7—
*10-12 Staff rounds at the Peter Bent Brigham Hospital

*Open to the medical profession
†Open to Fellows of the Massachusetts Medical Society

September 5, 6, 7—American Congress of Physical Therapy will meet at the Hotel Kansas City, Kansas City, Missouri. Program and circular of information may be secured by addressing American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Illinois.

September 17, 18, 19—Eleventh Clinical Congress of the Connecticut State Medical Society. For details address Dr. Creighton Barker, 129 Whitney Avenue, New Haven, Conn.

September 30-October 12—International Medical Postgraduate Courses in Berlin. See notice elsewhere on this page.

October 6-20—Seventh Annual Training Course For Medical Reservists at the Mayo Clinic. See page 441.

October 7-10—American Public Health Association will meet in Milwaukee, Wisconsin. For information address the American Public Health Association, 50 West 50th Street, New York City.

October 21-November 2—1935 Graduate Fortnight of the New York Academy of Medicine. See page 898, issue of May 9.

October 28-November 1—The Twenty-Fifth Clinical Congress of the American College of Surgeons. See page 1055, issue of May 30.

BOOK REVIEWS

The Nervous Patient. A frontier of internal medicine. Charles P. Emerson. 453 pp. Philadelphia, London, and Montreal: J. B. Lippincott Company. \$4.00.

This large book is a general review of various mechanisms of the body as they are reflected largely in nervous symptomatology. The approach is from the general field of medicine toward psychiatry, rather than from the field of psychiatry toward medicine. Because of this the book has considerable value, for it not only forms an interesting correlation between mental and nervous states and somatic disease, but, in addition, it reviews nearly all the common disease conditions of the body. Its chief weakness is its diffuseness. Had the author covered a less extensive field, the book would have been of more value. The short bibliographies following each chapter, moreover, are not a critical review of the most important literature on the subject.

Wish and Wladom Episodes in the vagaries of belief Joseph Jastrow 394 pp New York and London D Appleton-Century Company Inc. \$3.50

Professor Jastrow who is well known as a psychologist and the writer of popular books on the subject has made a careful review of the history of erratic beliefs many of which have had a wide influence in the course of civilization. Here one finds the story of ancient miracle-mongers the cult of the magnet, the ouija board psychics and ventriloquists and animal geniuses queer side-shows of sciences such as numerology palmistry the philosopher's stone auras and vibrations ectoplasm and other psychic phenomena. The book is well written and of considerable interest, for it contains much material not easily found elsewhere. Its value as a serious book however is much impaired by the lack of references. A few illustrations are of interest. As a popular study of the queer reactions of the human mind this book is to be recommended.

Martini's Principles and Practice of Physical Diagnosis Edited by Robert F. Loeb From the authorized translation by George J. Farber '13 pp Philadelphia, Montreal and London J. B. Lippincott Company

This volume is a translation of a German work and in 300 pages gives a comprehensive survey of what is essential in physical examination of the patient.

It is difficult to dissociate physical diagnosis disease pictures and physiology but by clinging to bare essentials the authors are able to explain the causes of physical signs without incorporating chapters from general medicine. The largest part of the book is devoted to examination of the heart and lungs with the combination of signs found in common diseases tabulated in convenient form.

If anything the book is too concise but with physical diagnosis taught largely in hospitals as it is today students will find a ready elucidation of the brief descriptions in their clinical material. The translators have added a very valuable textbook to clinical teaching in English.

Clinical Medicine Edited by E. B. Krumbhaar XV French Medicine M. Laignel-Lavastine and M. Raymond Molinier 187 pp New York Paul B. Hoeber Inc. \$3.50

This is a well written short, concise book on the history of French Medicine. It is one of a series of historical narratives aimed to give the reader the high spots of medical history with the hope that his interest in this field will be stimulated to further reading.

The chapters dealing with French Medicine during the Renaissance and the 17th and 18th centuries are very instructive and interesting. Short accounts of Ambroise Paré Paracelsus Rabelais and Fagot are given. The history of the Faculty of Medicine of Paris and the traditional rivalry between the surgeons of the above faculty and those

associated with the College of Saint-Côme is very fascinating.

The book is inexpensive, and can be read in a few hours.

Onchocerciasis With special reference to the Central American form of the disease. Contributions from the Department of Tropical Medicine and The Institute for Tropical Biology and Medicine. No. VI. Part I by Richard P. Strong. Part II by Jack H. Sandground. Part III by Joseph O. Bequaert. Part IV by Miguel Muñoz Ochoa. 234 pp Cambridge Harvard University Press

Pursuant to expeditions to Guatemala in 1931 and 1932 to study *Onchocerca coactiensis* the blinding filaria Dr. Richard P. Strong and his Associates have published an important monograph on Onchocerciasis.

Part I of the monograph was written by Strong himself. Among other topics, it deals with the distribution of onchocerciasis, its epidemiology and its clinical and pathological characteristics. Other sections of Part I describe the mode of transmission and discuss prophylaxis and treatment as well as other important aspects of onchocerciasis.

In Part II Jack H. Sandground discusses questions of taxonomy relating to the Genus *Onchocerca*.

Joseph O. Bequaert, in Part III deals with the various species of black flies or *Simuliidae* of Guatemala and devotes special attention to those found in the region in which onchocerciasis is endemic.

In Part IV Dr. Ochoa, of the Health Department of Guatemala contributes additional facts of epidemiological significance.

The monograph as a whole is the most comprehensive work that has yet appeared on onchocerciasis. It contains much new information points the way to control of the disease and possibly to its eradication. The authors found that, not one only, but at least three species of *Simulium* can transmit onchocerciasis. The various phases of the work are well illustrated with photographs, photomicrographs or colored plates.

Epidemics and Crowd Diseases. Major Greenwood 400 pp New York The Macmillan Company \$5.50

The author states that "this book is based on the instruction which I give to professional students at the London School of Hygiene and Tropical Medicine. But it is not a text book prepared with an eye to an examination syllabus. I have tried to cater to all educated men and women interested in the communal aspects of health and disease."

Such readers will find the book most interesting particularly in its historical aspects. Its style is philosophical. The author does not hesitate to qualify a previous deduction whenever the subsequent consideration of some other phase of the subject seems to make it desirable to do so. His style however often makes it difficult to tell

whether he is stating his own conclusions or presenting the ideas or methods of epidemiologists who assume that the factors, variable or otherwise, in the etiology of diseases which handicapped Hippocrates and Galen, have been eliminated by modern research to such an extent that, if a large group of human beings be exposed to infective agents with varying pathogenic possibilities and simultaneously subjected to mysterious biological variables, the consequences may be expressed by means of a mathematical formula

Whether with the author's endorsement or not, he shows us examples of the exercise of selectivity with respect to observations which serve to provide premises for logical conclusions, of a faith in records of morbidity and causes of death practically amounting to gullibility, and of the employment of mathematical devices in ways which remind one of the confused student who tries to solve an algebraic equation by differentiating it, and which leads the reader to expect to see that somebody has demonstrated how something can be intergraded to explain why epidemic manifestations of anterior poliomyelitis abruptly cease at the very season of the year when epidemics of personal contact diseases regularly begin

A difference in the point of view will likewise lead a reader of this book, who has felt personal responsibility, military or civil, for the maintenance of the health of large collections of human beings, to note the author's failure to observe that epidemic curves may be changed in shape by an intelligent practical recognition of the fact that contagious diseases are contagious before a positive diagnosis is possible, that the absence of positively diagnostic symptoms in the course of influenza and the freedom with which English physicians are accustomed to employ this term, make deductions from records of the relative prevalence of influenza in different English schools at different times extremely precarious, and also in connection with the same disease, that its mortality curve will be determined by the opportunity which those who may be stricken by a relatively harmless primary infection are given to acquire also hemolytic streptococci and other pathogenic potentialities with murderous proclivities as secondary invaders

Ideal Health or The Laws of Life and Health Alexander Bryce Third Edition 340 pp Baltimore William Wood & Company \$2 75

This book is one which should make a strong appeal to the younger practitioners, whose medical scholastic training of four years supplemented by two years at least of internship, has lacked a coherent, individualized course in the all important, everyday, rational work of taking good care of their bodies and preserving their health. These matters which vitally concern everybody are supposed to come to us by heredity, family training, earliest maternal instruction, nurses' upbringing, racial customs, traditions

and conventionalities, but most of all from home influences. Unfortunately these vital matters are left too much to chance, or one might say they are "everybody's business", and therefore they are nobody's special business

Dr Bryce, the author of this practical and useful little book, makes it his special business to sum up traditions, customs, racial habits, hygienic advice and theories, universal experiences, fads and scientific dicta, in twelve chapters. Each chapter has a sort of "golden text," or so-called "law" of health as a beginning. The first two chapters have the same law as a text, namely, Law I "Eat three meals each day of plain, wholesome, solid, nourishing food at or about the same time as far as possible." Chapter I is devoted to "Food in General" and Chapter II to a detailed consideration of food

The concluding chapter instead of illustrating any special law has for a motto "Do Unto Others as Ye Would that They Should Do Unto You," which is applicable enough for its subject, "Eugenics, the Science of Race Culture." Each of the twelve chapters concludes with an admirable, succinct and adequate summary

Dr Bryce does not seem to be strongly partisan in his views or devoted to any special theories, but discusses his various subjects (and they are numerous) from a very conservative, common sense standpoint, in a scholarly way without exuberance or overenthusiasm. Although a "total abstainer" he is not fanatical. He does not recommend the free and constant drinking of tea, coffee and alcohol, or the use of tobacco. One might say everything having to do with food, digestion, drink, sleep, rest, exercise, bathing, work, recreation, effect of the mind on the body, regularity, habit formation, air, cleanliness, clothing—in short everything that influences the body for good or evil, is very briefly considered by Dr Bryce, and an opinion in favor of or in opposition to, is definitely expressed

No new theories, facts or opinions are given but the sum of knowledge concerning the laws of health and how to keep well are presented, in clear, unmistakable language, in an attractive and convincing manner. The book is sure to make friends for itself

The American Illustrated Medical Dictionary A complete dictionary of the terms used in medicine, surgery, dentistry, pharmacy, chemistry, nursing, veterinary science, biology, medical biography, etc., with the pronunciation, derivation and definition W. A. Newman Dorland Seventeenth Edition 1573 pp Philadelphia and London W B Saunders Company \$7 00

An octavo volume of 1573 pages with 945 illustrations including 283 portraits, this edition represents three years' work under editorial supervision of the Staff of the American Medical Association

The text is clear, the paper and binding of excellent quality

Methods and Materials of Health Education. Jesse Felring Williams and Fannie B. Shaw 331 pp. New York: Thomas Nelson & Sons.

This book is written mainly for educators. In it the authors have shown how in a modern community, the school system may function decisively in promoting and safeguarding the health of the school population. For the authors "health education" signifies far more than mere instruction in personal hygiene. It means the integration of all the forces that the school may exert for the healthful mental and physical development of the school child.

In the first part, under the heading "Nature of the Child" are discussed the various phases of normal mental and physical growth and development, the factors which influence them and the chief causes of morbidity and mortality affecting children. Under the caption "Healthful School Living" are discussed the various health-promoting elements in the school environment. Under "Health Service" are discussed the subjects of physical examination, the correction of physical defects and the protection of the school population from communicable diseases including tests for susceptibility, prophylactic vaccinations and inoculations.

The section on "Health Instruction" deals with methods of imparting correct and useful instruction on personal hygiene and healthful living to school children.

The final section deals with a subject too often neglected, the personal health of the teacher. Statements in the book are supported by many references. This is a useful textbook for teachers.

Diet and Physical Efficiency. The influence of frequency of meals upon physical efficiency and industrial productivity. Howard W. Haggard and Leon A. Greenberg. 180 pp. New Haven: Yale University Press. \$3.00.

In an attempt to discover and formulate the best times of eating the investigators have observed and described in this book, the effects of variations in the consumption of meals on the blood sugar respiratory quotient, and physical efficiency of human beings. Most of the observations were made on factory workers and some of them were found to increase their productivity if five instead of three meals of much the same kind and amount of food were consumed. And the observations made on the blood sugar and respiratory quotient of children, students, and men and women doing light and heavy work, were also found advantageous, if more than three meals were ingested. The results of this study appear beneficial from the standpoint of productivity for a short period; on the other hand, as Americans are generally considered to overeat at three meals, such a regimen is likely to prove inimical to health if carried out for a long period. The book contains many figures and tables, a few illustrations, and a complete bibliography, and as it

is devoted to a special field of nutrition should be of interest to manufacturers and specialists in nutrition.

The International Medical Annual. A year book of treatment and practitioner's index 1935. Fifty-third year. Edited by H. Letheby Tidy and A. Rendle Short. 522 pp. Baltimore: William Wood & Company. \$6.00.

This volume edited by H. Letheby Tidy and A. Rendle Short, marks the thirty-third year of its publication. In the introduction the editors briefly review the major achievements of medicine in the past year. The main part of the book consists in an encyclopedically arranged review of the most important articles in the entire field of medical literature. The long list of contributors is selected from the leading men in their respective specialties in Great Britain.

The skill that has been shown in condensing such a great amount of material into one volume is truly remarkable. The generous use of illustrations, the bibliography accompanying each article, and the detailed general index add greatly to its practical value. It is a quick reference book that should prove useful to every practitioner of medicine.

Studies from the Rockefeller Institute for Medical Research Reprints. Volume 93. 588 pp. New York: The Rockefeller Institute for Medical Research. 1935.

There are two groups of articles of special interest in this volume containing a wide variety of material from the laboratories and hospital of the Rockefeller Institute. The first group concerns the work of Page onpressor and depressor substances obtained from the human blood. The work is done with unusual care and accuracy and should do much to clarify the rather confusing statements at present current in the literature.

The second group consists of the studies on the virus-induced tumor of rabbits reported by Peyton Rous and his collaborators. This Shope rabbit papilloma is one of the most interesting of the animal tumors owing to its known etiology and the marked similarity of the growth to certain neoplasms. At times this reaction to virus has some of the characteristics of a malignant neoplasm.

From the standpoint of those interested in legal medicine Landsteiner's able review "Forensic Application of Serologic Individuality Tests" will be of definite interest.

Diseases of Children. Edited by Hugh Thursfield and Donald Paterson. Third Edition. 1152 pp. Baltimore: William Wood & Company. \$10.00.

Thursfield and Paterson's third edition of *Diseases of Children* is not just another book on a subject already very satisfactorily covered in English. It is one of the most comprehensive of pediatric texts

and is written by thirty six contributors who have in this edition again successfully added the important advances in this field. The reviewer feels that this textbook can be especially recommended to American students and physicians interested in this subject. The reader is always impressed by Cameron's contributions. This author's presentation of "Functional Diseases of the Nervous System" is illustrative of many almost classical textbook expositions of clinical subjects found in this volume.

Recording of Local Health Work W F Walker and Carolina R Randolph 275 pp New York The Commonwealth Fund, London Humphrey Milford, Oxford University Press \$2 00

Obviously the records kept by local health organizations are the only means for evaluating the effectiveness of the work, determining the trends of communicable and other diseases and of demonstrating to taxpayers and appropriating bodies the dividends on their investment in health protection.

Yet the inadequacy of the records kept are too often the weakness of an otherwise aggressive and effective local health organization. By the presentation of the system of record keeping set forth in their book, Dr Walker and Miss Randolph have made a useful contribution to the Science of Public Health Administration. The book constitutes a complete manual of record keeping in local health work. A series of standard forms for records approved by the Committee on Administrative Practice of the American Public Health Association are presented with the necessary explanatory comments. This is a book which merits a place on the bookshelves of local health offices. The practical application of its principles of record keeping would give the local health officer a firm grasp on the local health situation and point the way to obvious means for strengthening and improving local health organizations. Reports based on such records would give the State Health Officer an accurate picture of the activities of local health organizations and greatly facilitate the work of supervision, standardization and coordination.

The Surgical Clinics of North America June, 1935 Volume 15, Number 3 Chicago Number 782 pp Philadelphia and London W B Saunders Company Paper, \$12 00, Cloth, \$16 00 net

The feature of this issue of the Surgical Clinics is a symposium on fractures. Speed reports two cases of unusual nerve involvement, one with a fracture of the head of the fibula and the other following an elbow fracture with overgrowth of the head of the radius. Strauss presents a rather detailed discussion of fracture of the femur in children, emphasizing the value of Russell traction. Some new points in the treatment of fractures of the sternum are brought out by Ellis.

His careful methods of examining the back are

outlined by Magnuson while Kreuscher discusses the surgical aspects of backache.

Among the other more interesting clinics are one by Bettman on injuries of the chest and Bevan's able presentation of the problem of the treatment of peritonitis.

The other clinics include several that help make this issue one of practical value to all surgeons.

The Story of Medicine in the Middle Ages David Riesman 402 pp New York Paul B Hoeber, Inc \$5 00

The revival of scholasticism in philosophical circles in these days is accompanied by renewed interest in other phases of medieval thought and life as shown by the biographies, historical novels and even the rewriting of history itself. Since scholasticism is the forerunner of modern scientific thought it is natural that a review of medicine in the Middle Ages should be made.

This book—intended largely as a text for medical students—tells the story of medieval medicine in an interesting although familiar manner. Even though the presentation is not so sympathetic with those not-so-distant years, as one might wish, the facts presented closely agree with the writings of other serious students of those times (Sudhoff, Walsh, Sigerist, etc.), and the differences lie in emphasis and interpretation. Most of the information can be obtained, in a scattered way, elsewhere, but the material is so pleasantly assembled and, in addition to the factual medical history, the pages are filled with so many interesting digressions, anecdotes and short dissertations on universities, guilds, monasticism and other aspects of medieval life that had important bearings on medicine, that the student accustomed to thinking only of the feudalism and tenure of the Dark Ages, will find the book refreshing. It is thoroughly indexed and adequately illustrated and ought to serve its purpose rather well.

L'Examen du Malade Guide clinique de l'étudiant et du médecin Médecine, Chirurgie, Obstétrique, Neurologie et Spécialités P Delmas, G Giraud, et al 318 pp Paris Masson et Cie 30 fr

This small volume of three hundred and eighteen pages on the examination of the patient is extremely well done. While not a treatise on diagnosis or physical diagnosis, the book should serve as a useful guide to students and general practitioners. It is indeed interesting to note the stress placed on "Observation" or, what we call inspection, and the signs that can be observed in various diseases from inspection alone.

The specialties such as ear, nose, throat, gynecology, neurology, pediatrics and others are adequately discussed in reference to signs and symptoms, and presented in a very practical manner.

The last chapter is devoted to laboratory procedures, and the authors mention the precautions one should take in the interpretation of them.

The Massachusetts Medical Society

SECTION OF SURGERY

Ball Room Assembly, Hotel Statler Boston, Tuesday, June 4, 1935, 9.15 A.M.

PRESIDING

Ralph W. French, Fall River Chairman.
E. Parker Hayden, Boston, Secretary

CHAIRMAN FRENCH: If the meeting will come to order we will begin. Before introducing the first speaker I will state that this year we have made some change from the procedure heretofore followed. Instead of listening to four papers each followed by discussion this year we have provided for eight papers and no discussion. It is obvious that

we could not have any discussion and listen to that number of papers too. We await your reaction to this change in program.

The first paper this morning is entitled "Two Hundred Acute Perforated Ulcers of the Stomach and Duodenum from the Boston City Hospital," by Dr. William Reid Morrison of Boston, Associate Professor of Surgery at the Boston University School of Medicine and Visiting Surgeon Boston City Hospital.

TWO HUNDRED ACUTE PERFORATED ULCERS OF THE STOMACH AND DUODENUM FROM THE BOSTON CITY HOSPITAL*

BY WILLIAM REID MORRISON, M.D.†

ONE of the most serious of surgical conditions which medical men encounter in their practice, is perforation of an ulcer of the stomach or duodenum.

Since the Boston City Hospital admits more acute surgical emergencies than any other hospital in New England a review of two hundred recent consecutive cases may reveal findings of value. The writer has been particularly interested in this type of stomach surgery, having been given by the surgical staff of the Boston City Hospital the special assignment for study and operation of all perforated ulcers of the stomach and duodenum on the five general surgical services some years ago.

An average of forty to fifty acute perforations are operated upon each year at the hospital, these cases under consideration comprise admissions from the year 1930 to 1935.

The ages of these patients varied from fifteen to seventy eight years. Perforations may occur at any age cases are on record in the very young and very old, but the decade in which our perforations most frequently occurred was between thirty five and forty five years of age.

Women seldom develop perforated ulcers, there were but five females to one hundred and ninety five males.

One hundred and fifty five were typical obvious acute perforations. The atypical case was diagnosed cholecystitis eight times, appendicitis nineteen times, other diagnoses were pan-

creatitis, peritonitis, alcoholic gastritis, cardiac disease, intestinal obstruction, renal calculus, and surgical observation.

The typical acute case has a history of ulcer for years, described as persistent indigestion, dyspepsia, distress in the pit of the stomach, etc. in about seventy five per cent of the series. Forty six, about twenty five per cent, gave no history of prior stomach trouble whatever the acute perforation coming out of a clear sky. Twenty nine patients did not vomit at perforation, and eighteen had neither nausea nor vomiting. Therefore one should not hesitate to make a diagnosis of perforation, in the face of positive physical findings with absence of prior symptoms or absence of vomiting. To be sure everyone has had experience with gas and indigestion at times following indiscretions in diet.

Sudden, terrific, pain in the upper abdomen, usually the epigastrium often associated with nausea and vomiting doubles the patient up and the victim writhes in intense agony. Evidence of surgical shock is present at the time of perforation but in several hours the patient recovers from the shock symptoms, and may be up and about the house smoking a cigarette or sitting in a chair. The epigastric pain may be referred to the right or left shoulder, to the umbilicus or right lower quadrant.

Most of our patients, one hundred and thirty two had normal temperature, pulse and respiration, on being admitted to the hospital a matter of several hours after perforation, having recovered from their surgical shock. Sixty-eight had elevation of pulse and temperature above

*Read at the Annual Meeting of the Massachusetts Medical Society Section of Surgery June 4, 1935.
†At present, William R. Morrison, Visiting Surgeon Boston City Hospital, Second Surgical Service. For record and address of author see This Week Issue page 499.

one hundred It is most important that general practitioners be not misled by normal or nearly normal temperature, pulse and respiration, and as above mentioned, the frequent lack of prior ulcer story

The interval between perforation and operation is of vital importance, because the earlier the patient is operated on, after recovering from shock, the better the chance for recovery, and best end result One hundred and forty-four perforations were operated on within six hours Most cases operated on within six to eight hours or less have an excellent result, our shortest interval was one and one-half hours, the longest was thirty-six hours Fatal results are caused by delay on the part of the patient, family doctor, or surgeon Administration of home remedies, drug store advice, morphine administered to allay the pain, and allow procrastination, often result in the death of the patient Incorrect diagnosis of "unknown gastrointestinal disease", "heart trouble", intestinal gripe, or intestinal obstruction interferes with proper care

It is quite significant that our recent cases have been better diagnosed, and sent into the hospital for operation much earlier, than in the last decade, demonstrating better knowledge and treatment of this emergency by the general practitioner

Palpation of the abdomen, with the board-like rigidity caused by involuntary abdominal spasm, associated with acute tenderness, particularly in the epigastrium, is of prime importance General physical examination of the patient should not be neglected If the systolic blood pressure is below fifty to eighty millimeters of mercury, it is obvious that the patient is too poor a risk for operation, until the blood pressure is raised The writer was the first surgeon at the Boston City Hospital to demonstrate air in the peritoneal cavity, which had escaped from the stomach or duodenum through the perforation

Fluoroscopic or x-ray pictures of the patient in the erect position may show a positive pneumoperitoneum, the presence of air in the peritoneal cavity, usually between the liver and diaphragm which effectively establishes the diagnosis Absence of air does not rule out perforation Pneumoperitoneum was present in about half of the cases examined by x-ray It is apparent that any patient in poor condition should not be x-rayed at all Air may be demonstrated between the spleen and diaphragm, or along the side of the abdominal wall, with the patient lying on the side The air may escape into the peritoneal cavity from the perforation in either the stomach, or intestines A large layer of air may be found under the right and left portions of the diaphragm, or merely a small bubble may appear

The white blood count may be raised, but if

normal, it does not rule out the presence of perforation

The diagnosis of a typical case is made on the history of the case, the usual terrifying epigastric pain, tenderness in the epigastrium, or all over the abdomen, board-like rigidity of the abdominal muscles, and if present, pneumoperitoneum Absence of liver dullness, and tenderness in the pelvis on rectal or vaginal examination, with elevation of white blood count, aid in making a correct diagnosis

Preoperative care consists of shock treatment particularly subcutaneous injection of salt solution or intravenous glucose, or blood transfusion

Ether anesthesia was given in 100 cases, spinal injections in ninety-five, local anesthesia in two cases, which were very poor operative risks Three patients were not operated on Our experience has been to use spinal anesthesia in the better risk patient, and not in the poor risk class

In most of this series a right rectus incision was used, a transverse incision is preferable for local anesthesia.

A notation of the presence or absence of air coming out of the belly should be made Filling the abdominal wound with salt solution, just prior to opening the peritoneum, allows air to bubble out, if present

Presence of free fluid and its type should be observed, and a culture should be taken of the peritoneal cavity which is usually negative The type of fluid in the belly depends on what the stomach or duodenum contained at the time of perforation Thin mucoid dish-water stomach contents containing meat, baked beans, milk, etc, may be found, or bile stained pea soup varieties

At perforation, the stomach contents are shunted by the root of the mesentery, toward the right lower quadrant, then into the pelvis, accounting for the frequency of right lower quadrant pain simulating appendicitis

The escaped stomach contents adjacent to the abdominal wound should be removed with gauze strips Certain surgeons insert a mechanical sucker into the pelvis to remove stomach contents The writer feels that this is an unnecessary procedure, for it injures the intestines, and is not needed, for a chemical peritonitis is present in the early cases, and the peritoneum takes care of what little infection may be present

In this series of two hundred cases, a single perforation was found in each instance We have a case on record which had two acute perforations at the same time, one of which was overlooked, therefore the surgeon should hunt for more than one perforation Re-perforation occurred twice

Perforations usually occur at the pylorus,

about an inch on either the duodenal or gastric side, and on the anterior surface of the stomach or duodenum.

Less frequently they are found on the posterior wall of the stomach, which occurred in two cases or on the lesser curvature of the stomach in twenty-five cases, rarely on the gastric greater curvature with only two cases of this type in this series. The perforation is usually the diameter of a slate pencil and is surrounded by an area of induration the size of a silver quarter. In none of this series was bleeding noted. I have seen changed blood in the peritoneal cavity at the site of perforation but twice.

The perforation was closed by either purse-string or mattress sutures, or both in our cases. The ulcer may be excised with either knife or cautery, or let alone. No operative procedure was needed in one case since the great omentum closed the perforation.

The perforation may be wholly or partly sealed up by the omentum, intestine, liver gall bladder, or by a piece of food, or by fibrin.

The location of the perforation was not found in one case, although baked beans were floating among the intestines in the free peritoneal cavity. At autopsy five days later, the site of perforation could not be found by Dr. Mallory or his assistants.

The exact site of perforation cannot be determined in most cases, as the pylorus usually cannot be palpated because of adjacent induration and the pyloric vein is usually obliterated.

Excision of the indurated area with the perforation, allows the surgeon to insert a finger inside the stomach and duodenum, definitely locating the site of perforation, and allowing palpation for other ulcers, if present. Closure by interrupted mattress gastrointestinal sutures of the normal stomach or duodenal wall over the site of perforation is the procedure of choice.

Attempts to suture through the indurated area are futile as the stitch cuts through the porky tissue if it is pulled tight enough to close the perforation. The great omentum is usually sutured over the site of perforation.

Twenty-two cases were closed without drainage. One hundred and seventy-eight were drained. The abdominal wound or a stab wound may be used for drainage.

The multiple drained cases may develop more residual abscesses than those undrained.

The writer believes that cases which have been perforated under six to eight hours in which the intestines are smooth and shiny and not dull and lustreless should have the abdomen closed without drainage. If a drain is inserted, it is best placed as a suprapubic wick

to the pelvis. The writer does not believe that the abdominal wound should be drained at all, as it invites evisceration, or a gastric or duodenal fistula. Multiple drainage is to be avoided as unnecessary but the patient often survives despite it.

In such cases the peritoneum is closed by the writer with continuous catgut sutures then the wound is washed out with salt solution to clean out stomach contents and bacteria. Other wise semiseptic wounds result, with evisceration occasionally. In six cases of this series, rupture of the abdominal wound occurred. Stay sutures should not be removed under fourteen days, and adequate support for stitches should be given by the scultetus or many tailed band age.

If the pylorus is occluded, a posterior gastroenterostomy may be needed, a pyloroplasty may be done rather than posterior gastroenterostomy, if the outlet of the stomach is narrowed by the operative procedure.

After treatment consists of head rest, four hours having elapsed in spinal anesthesia cases nothing by mouth for twenty-four hours, then sips of hot water, sips of cold water later followed by equal parts of milk and lime water then a Sippy diet. Some surgeons prefer to insert a duodenal tube through the nose into the stomach for several days, postoperatively to avoid vomiting.

There were forty-three deaths, a mortality of about twenty-one per cent.

Complications were general peritonitis, bronchopneumonia, pelvic abscess, surgical shock, infection of the wound, cardiac disease, gastric and duodenal fistulae. Other sequelae were septic parotitis, pulmonary tuberculosis, embolism, empyema, gastritis, cellulitis of the neck, psychosis, liver abscess and jejunostomy for intestinal obstruction.

Forty-six patients returned for follow-up, about twenty-five per cent of the series. Forty-three had a satisfactory result, three were unrelieved, despite being on a careful medical diet.

CHAIRMAN FRENCH: We will pause for a moment just to name a Nominating Committee who will bring in names for Chairman and Secretary for this Section for next year. I will name Dr. William O. Faxon, Dr. Lester Whitaker and Dr. G. A. Moore.

The next paper is entitled "The Treatment of Recurrent Varicose Ulcer" by Dr. Edward A. Edwards, of Brookline.

DR. DAVID CHEEVER: My Chairman, may I ask whether it would be wise to have a call for discussion?

CHAIRMAN FRENCH: We had planned Dr. Cheever not to have any discussion and just try it out, something different this year. To have eight papers without any discussion we thought might be more interesting than to have four papers with discussion.

THE TREATMENT OF THE RECURRENT VARICOSE ULCER*

BY EDWARD A. EDWARDS, M D †

NO varicose ulcer, whether or not it is seen for the first time, can be rationally managed except by treatment of the underlying cause, i.e., the varicose veins. Any other treatment directed to the ulcer itself, such as the application of salves, pressure dressings or bed rest, merely acts in a symptomatic fashion, healing the ulcer temporarily but giving no protection against recurrence.

One cannot always see the varicose veins in the ulcerated limb. The really bad limb is apt to be greatly swollen and edematous to the point of board-like induration. In consultations on such a limb, one hears much talk of "deep varicose veins" with the inference that the varicosities are beneath the deep fascia, a condition that actually does not exist unless the patient has the unusual condition of congenital venous angioma. Or the referring physician may call the condition by the continental name of "ulcus cruris", a term that infers that ulcers of the leg can exist as a peculiar primary state. To speak in such terms is not to take cognizance of a mass of evidence from dissections and other visual preparations, and serves merely to detract the surgeon from demonstrating the exact pathology and instituting a rational line of treatment.

On seeing the patient for the first time, the examiner must try to satisfy himself whether the ulcer has the characteristics of a varicose ulcer. A varicose ulcer is usually situated in the lower third of the leg, has an irregular, dirty, and cyanotic base, is surrounded by brownish pigmentation and edema. If one rules out trauma, syphilis, and diabetes such an ulcer must then be called varicose, remembering that any one of these conditions may contribute to a varicose ulceration. Having therefore, labeled the ulcer varicose, the surgeon can then try to determine the exact state of the veins in the given case.

Our experience at the Boston City Hospital has convinced us that the treatment of recurrent varicose ulcers is simply the treatment of recurrent varicose veins. Through the study of these cases of recurrent varicose veins we have evolved certain criteria of treatment which I have discussed fully in a previous paper¹.

We had noticed, in common with previous observers, that the processes of recanalization and widening of previously normal veins went on

*Read in abbreviated form at the Annual Meeting at the Massachusetts Medical Society Section of Surgery June 4 1935 and here printed in extenso. From the Circulatory Clinic of the Boston City Hospital and the Dept. of Surgery Tufts Medical School. Aided by a grant from the Charlestown Research Fund Tufts College Medical School.

†Edwards Edward A.—Assistant in Surgery and member of the Circulatory Clinic Boston City Hospital. For record and address of author see "This Week's Issue" page 499.

most swiftly and completely in the severe cases of varices^{2,3} (Figures 1, 2, 3). These severe cases of varices are those in whom there is a dilatation of the great saphenous vein, with a resulting valvular incompetence and a down-

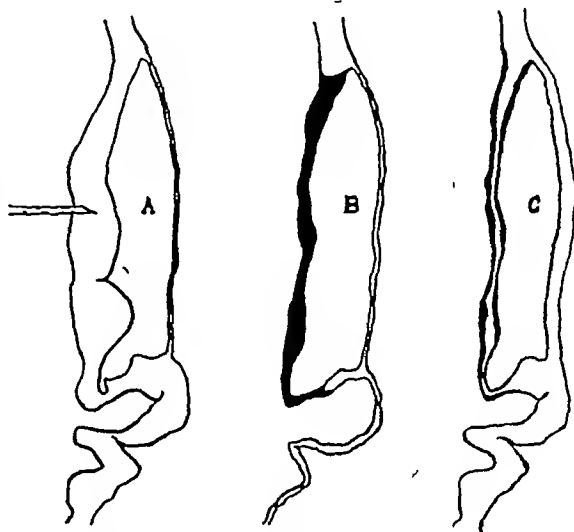

FIGURE 1 The two modes of recurrence of a varix

In A sclerosing solution is being injected into the middle of a dilated venous trunk. A normal collateral also communicates with the varix below. In B the entire dilated trunk is obliterated and the varix below is collapsed. In C the varix has been reformed by (1) recanalization of the previously sclerosed trunk and (2) dilation of the previously small collateral. Either or both of these two processes may occur in any given case. (From Surg. Gynec. Obst. 59: 916, 1934.)

ward flow of blood. That is, a so-called singly positive Trendelenburg test*. For these cases we section and ligate the great saphenous vein at the sapheno-femoral junction, and then deal in the same way with every one of the entering tributaries at this point (Fig. 2).

This section of the saphenous and all its tributaries at this highest level must be the starting point of treatment of the severe varices, and insures against recurrence. The veins below are subsequently treated by injection.

The other two classes of varices which I consider of less severity are as follows. First, small

*Trendelenburg's description reads: "Lay the patient flat lift the leg up vertically the varices empty. Now compress the saphena magna with the finger. Stand him up quickly. The varices fill slowly but not so much as previously. Now let the finger go and the varices fill very quickly and fully by a column of blood which is seen to shoot downward in the saphena magna."

This is now commonly called a singly positive Trendelenburg test. It denotes insufficiency of the saphenous valves.

The term negative Trendelenburg test refers to that result in the above experiment in which there is no increased or rapid distention of the varices either before or after the compressing finger is removed from the saphenous. It indicates competency of the valves of the saphenous as well as of the perforating veins connecting the deep with the superficial veins.

A doubly positive Trendelenburg test shows itself as a quick filling of the varices before the release of the saphenous as well as a downward reflux after its release. It indicates (1) incompetency of the valves of the perforating veins with a flow from the deep to the superficial veins (the reverse of normal) as well as (2) incompetence of the valves of the saphenous veins.

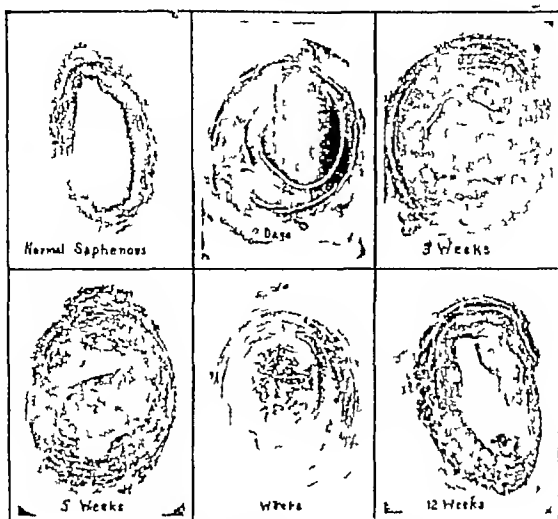

FIGURE 2 The mechanism of recanalization

Two days after injury the lumen of the vein is filled with blood. At three weeks the clot is still present and the spaces are appearing. At five weeks the clot is shrinking still more. At eight weeks the clot has formed a gross mass of organized tissue. At twelve weeks the lumen is completely recanalized, but the normal saphenous vein wall remains greatly thickened.

FIGURE 3 Regeneration of saphenous varices by dilation of previously normal collateral veins.
The patient had had an excision of the saphenous up to the middle of the thigh. The injecting needle is shown in the proximal stump of the saphenous. (From New Eng J Med. 99: 1227-1232.)

varices of the great saphenous vein when that vein does not show a reflux of blood, and secondly all varices of the lesser saphenous vein whether large or small. Delbet⁴, and more recently McPheeters⁵ have demonstrated the high pressures that exist in the first class of varices noted and also the tremendous increases incident to exercise standing coughing etc. Delbet further made the statement that varicose ulcer occurs only in those patients with very high venous pressure in the leg. Additional pressure studies are being made which would indicate that these high pressures occur exclusively in the first class of varices noted above. Clinically, I have been looking for but have not yet found, any single case of ulcer occurring when the varices were of the lesser saphenous vein or when the greater saphenous vein did not show valvular incompetence and a positive Trendelenburg test.

The suggestion comes to mind that the vein in any case of ulcer should first be ligated without bothering to find out the state of the varices. We have, however, not done this, but have in each case of ulcer attempted to determine the exact state of the varices, and the result has been that in each case of ulcer we have because of the state of the veins ligated the saphenous vein and have subsequently injected the varices

below The only exceptions to this rule have been made in patients who have been very feeble from senility or other disease In these patients we have had to be content with repeated injections of the veins Occasionally also one meets a patient in whom there is considerable active infection with inguinal lymphadenitis In these patients I have deemed it wiser to try to clear up some of the infection before operating rather than to cut through infected lymphatics We have, therefore, carried these patients along for a few weeks with injections several inches away from the ulcer and frequent cleansing of the leg with hot soap and water, alcohol, ether, and then antiseptic dressings of alcohol or ammoniated mercury ointment or hot chlorinate dressings Then, when

dissection, as noted above, obtains all the tributaries of the saphenous, both below and above the fossa, and the operation is not completed until the entire circumference of the fossa is explored down to the deep fascia (Fig 4)

I have abandoned the injection on the operating table of sclerosing fluid into the distal segment of the saphenous for two reasons first, leakage of the fluid into the wound may cause induration and slow healing, and secondly, the resulting venitis is painful, and because it adds to the patient's discomfort, it prevents the patient from adequately exercising the limb This exercise is, I believe, necessary to avoid the possibility of stagnation thrombosis in the veins of the leg, which, if it proceeds to the deep veins may give embolism To avoid the stagnation I

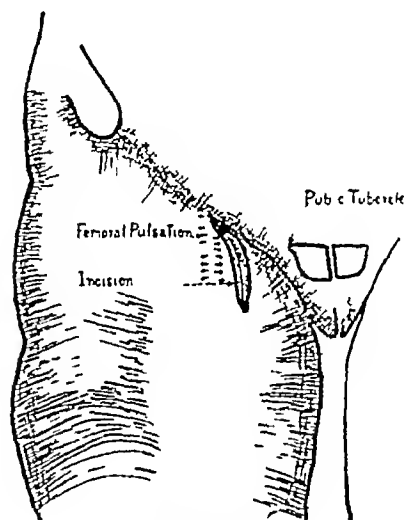

FIGURE 4a

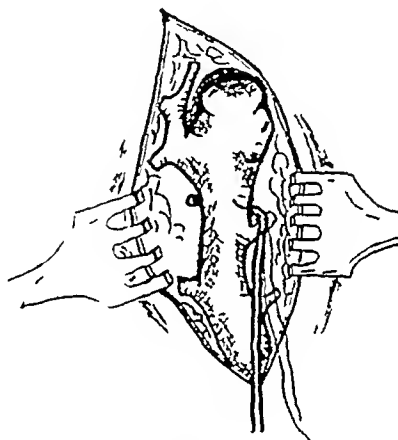

FIGURE 4b

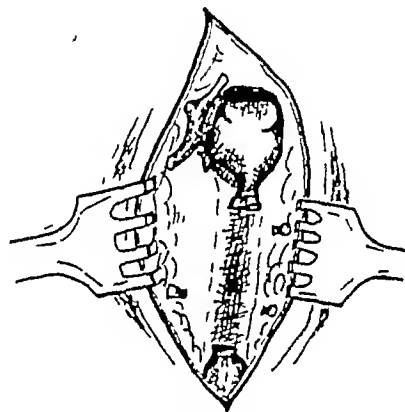

FIGURE 4c

FIGURE 4 The technic of high saphenous ligation In 4a is shown the location of the incision In 4b the saphenous is seen cleared at its termination in the femoral vein In 4c the saphenous tributaries have been cut across and ligated and a portion of the saphenous proper has been excised

by these means the infection is reduced and the lymph nodes have become smaller, the ligation is done and the remainder of the treatment continued

The ligation is carried out in the hospital under local anesthesia The procedure is one which has been well described by Homans⁶, Faxon⁷, and me¹ The essential point is to make sure that all tributaries are obtained and cut To this end the incision must be made high at the sapheno-femoral junction I have determined the average location of the sapheno-femoral junction by definite measurements recorded in my previous paper I prefer a roughly vertical or "hockey stick" incision This incision cuts through a minimum of lymphatics The incision starts in the line of the groin, somewhat lateral to the saphenous termination and then curves medially and downward for three or more inches It is placed less than two fingerbreadths lateral to the pubic tubercle, and one fingerbreadth medial to the femoral artery The

instruct the patient to raise each leg in the air and "bicycle ride" the leg six times This, the patient first does on the operating table and then every hour while in bed In bed also the legs are supported by a pillow so that the return flow should be favored The patient is not allowed a bedpan or urinal, but is forced to walk to the lavatory The day after operation the patient is instructed to get out of bed and encouraged to walk He is told to keep the leg up on a stool when sitting down, and is discharged this next day after operation, unless he comes from out of town, when I prefer to keep him a few more days

Although the use of elastic bandages while the patient is in bed is probably harmful because of stagnation of blood, it is distinctly beneficial once the patient gets up, and it should be almost routine As soon as the patient is sufficiently comfortable, usually within one or two weeks, the injections are begun I prefer sodium morrhuate (5 per cent) from 5 to 4 cc

at any one site, sometimes giving a total of 10 or 15 cc. These injections are started far from the ulcer and if no great venitis follows, the injections gradually are given nearer and nearer to the ulcer, until finally the veins in the ulcer bed are treated.

About ten per cent of extremities with ulcers show a doubly positive Trendelenburg test that is there is incompetence not only of the valves of the saphenous, but also of the perforating veins. These are especially stubborn cases. It has been advocated in the past to excise these incompetent perforators. While we have done this operation in three cases, I do not feel that it should be undertaken very frequently. The incision usually runs through indurated tissue and may be extremely hard to heal. As a matter of practice, one finds that after the ligation, and perhaps after a few injections, the perforating vein becomes sufficiently collapsed so that its valve is competent and the overlying varix may be successfully sclerosed, although it may take several repeated injections to do this.

RESULTS AT THE BOSTON CITY HOSPITAL

The Circulatory Clinic at the Boston City Hospital was organized in 1929. At that time there were, of course the usual large number of patients with severe, old, varicose ulcers. The injection treatment was responsible for the cleaning up of the majority of these cases in a very short time. Of course, this treatment was for these cases not permanent. There was, nevertheless, a fairly large group of patients who, by 1931 and '32 had been treated in the Circulatory Clinic with injections, and in whom the ulcers refused to heal. The duration of the ulceration varied up to twenty-seven years. In some of these patients new ulcers had come during the course of treatment. There were thirty-one of these patients when we first started doing ligations. Some of these patients had received over 100 injections and had in addition come to the clinic for treatment by dressing, or the application of Unna's casts, an additional 100 to 150 times. There were several cases who had also at some time previously had excision or stripping operations done for their veins.

Every one of these patients, without exception healed after ligation and subsequent injections. I wish to point out that we have not had to excise or skin graft a single ulcer. Most patients went home the day after operation. Occasionally one stayed in one or two weeks because of sepsis. Almost every patient returned to his or her work in a few days after operation. The mass effect of this type of treatment was well shown in the "cleaning up" of the clinic. Before we started doing ligations the patients were on a waiting list eight or nine months before starting their treatment, and we had thirty to forty patients on each clinic day. A few months after we started the ligations,

there was no waiting list, and we treated only eighteen to twenty five patients on each clinic day.

It is true that many of these ulcers did not completely heal until six months after the ligation, but most of them felt very much relieved within one or two weeks. The edema quickly diminished and the patient was comfortable. The number of injections necessary after the ligation was very small, varying from no injections in some cases and averaging about six. The ulcer was usually dressed with nothing more than seventy per cent alcohol. Occasionally balsam of Peru was used. Scarlet red was used by some of the men in the clinic, but I personally believe it to be too irritating and I do not use it. It may be noted that these patients were for the most part comfortable and at work during the period of healing. This is in contrast to the several weeks' stay in bed that is necessary when ulcers are excised, further more, it puts the method to the test, since obviously any method of treatment that can be efficient with the patient working and on his feet would seem to give more promise of permanency.

SPECIAL POINTS IN EXAMINATION

It is apparently not superfluous to point out again that syphilis can give ulcers of the legs. Diabetes, plus a little local trauma or infection, can initiate an ulcer which may be stubborn to heal. Either of these two conditions may coexist with varicose veins. Certainly their presence should be ruled out. I have seen two ischiatic legs in which the diagnosis was made by the finding of periostitis by x-ray, while the serum reaction was negative. I have seen a chronic ulcer in a myxedemic which cleared up promptly after the administration of thyroid. The influence of focal infection, though impossible to evaluate, is probably considerable in the patient with a frank case of pyorrhea or many apical abscesses, broken off dental roots, etc. It would seem that these should be attended to, in order to improve the patient's general condition if for no other reason.

Sometimes it is difficult to find varices in the leg. Many of the ulcers are surrounded by wide zones of board like induration. The veins can rarely be seen, but usually can be felt as soft areas within the indurated tissue. In doing the Trendelenburg test in a case of this sort, the filling of the vein must be determined by feeling the amount of tension in it with the finger, rather than by seeing it fill. The continuity of the veins in the leg with the saphenous in the thigh can oftentimes be determined by placing one hand over the line of the saphenous in the thigh, and slapping the veins below rather sharply. In this way a thrill is produced which is transmitted to the upper hand by the blood ('Percussion Pulse Transmitted' of McPheeters). This thrill can

probably not be transmitted through a normal-sized vein

For purposes of clarifying treatment and demonstrating palpable veins to others, I have made use of x-ray visualization of the veins after the injection of an opaque medium (vasography), and in other cases, infra-red photography. Both of these graphic methods illustrate the venous pattern of the recurrent veins (Figs 5 and 6). It can be readily understood that after excision of the saphenous and its main branches, as well as after thorough injection of the veins, that the veins, having lost their principal trunks, pursue a tortuous and festooned course

I have seen about twenty patients who have suffered from small ulcers in the presence of occlusion of the femoral or iliac veins, or of the inferior vena cava. Occlusion of the deep veins should be suspected if the patient gives a history of painful swelling of the leg after operation, typhoid fever, and other acute infections, or after obstetrical delivery. It can be diagnosed by seeing large collateral veins carrying blood upward from the saphenofemoral junction, over the abdomen, to end in the region of the axilla, axillae and back. It has been possible in several of these patients to confirm the diagnosis by vasography⁸ (Fig 7). In such patients the superficial veins at the sapheno-

Case A. K. Boston City Hospital number 196670. Injections were started in 1930 and by June 1933 the patient had received 80 injections and had been treated by Unna's casts and other dressings an additional 146 times.

5a shows the leg before ligation. No varices were visible. Only a few small varices were palpable in the calf. A venogram 5b shows recurrence of the saphenous. Saph. dilation and valvular incompetence of the perforating vein PV leading to the deep posterior tibial veins DV and the presence of normal valves 'V' in these deep veins. The venogram was made with the patient lying down and with venous tourniquet applied. (From New Eng J Med 209: 1337, 1933.)

High ligation of the saphenous was performed and the ulcer dressed with simple alcohol and gauze. The patient returned to his work as cook five days after the operation. Five weeks later the ulcer was healed. 5c

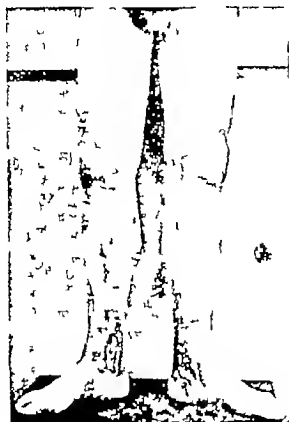

FIGURE 6a

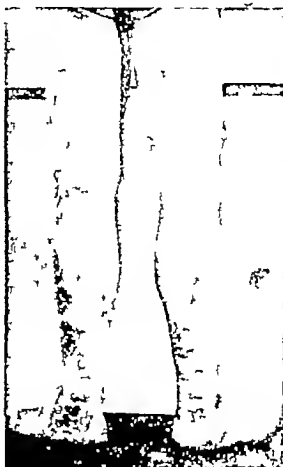

FIGURE 6b

FIGURE 6c

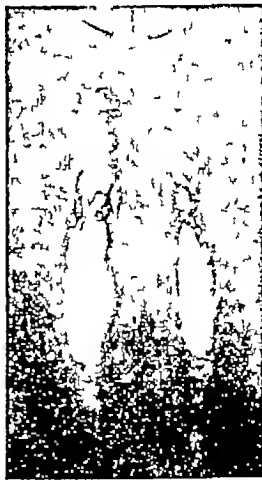

FIGURE 6d

FIGURE 6 The venous pattern in recurrent ulcer

"6a" and "6b" are ordinary photographs (panchromatic film) of a patient who had ulcers for 25 years. Excision of both great saphenous veins was performed 10 years ago. During the past 5 years the patient had 100 to 125 injections. Only in "6b" is any skin visible red photograph of the same patient. Because of the extension and sclerosis of the main venous trunks the only veins remaining are narrow collaterals spreading from the saphenous stump in a tortuous and festooned manner.

FIGURE 7a

FIGURE 7b

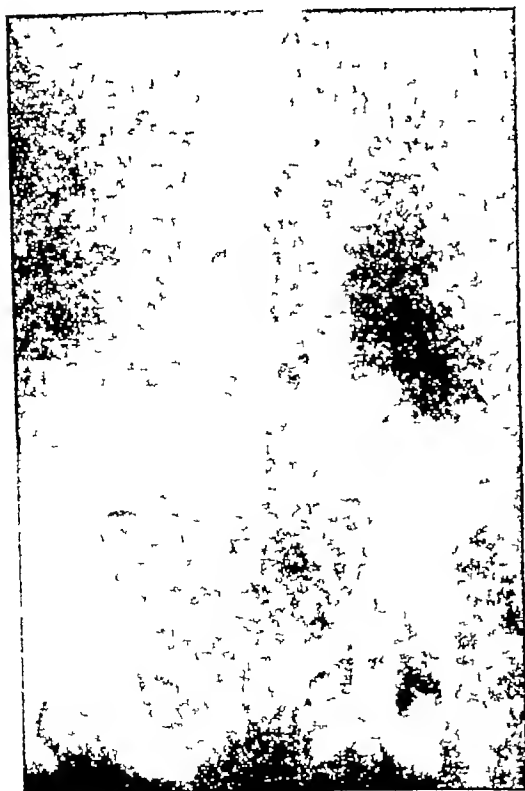

FIGURE 7c

FIGURE 7. A case of varices due to thrombosis of the inferior vena cava giving recurrent ulcer. D. S. Boston City Hospital number 1800. Thrombosis of the inferior vena cava of 16 years duration. The ulceration of the legs is successfully controlled by an occasional injection of the varices in the legs. Such a patient should never have any injections or surgery done in the upper third of the thigh. 7b and 7c show the venograms of this patient made by injecting Skiodan into the femoral veins. The occlusion of the vena cava is still complete, no iliac shadow being seen. All of the injected material flows back along the needle to run upward by way of the superficial epigastric and circumflex iliac veins.

femoral junction carry all, or a great part of the blood away from the inferior extremity and must not be removed or sclerosed. These patients have a permanent defect. They must wear a supportive stocking or bandage permanently. If the deep veins of the lower leg can be shown to be patent, then it is proper to inject the superficial varices as high as the middle of the thigh. I have seen several such patients who have returned for yearly or half-yearly injections and whose ulcers have in this way remained healed.

CONCLUSIONS

The successful treatment of recurrent varicose ulcer depends upon making sure of the diagnosis, and then treating the underlying cause, i.e., varicose veins. It has been demonstrated theoretically and practically that the varices are of the severest type when there is an ulcer pres-

ent For this type of varix the most successful treatment yet evolved is a section and ligation of the saphenous vein and its tributaries at the sapheno-femoral junction. This is then followed by subsequent injections. Using this method of treatment we have been able at the Boston City Hospital completely to heal every case of varicose ulcer including cases that had failed to heal after a thorough course of injections as well as the usual local applications.

It may be concluded that when a recurrent case of ulcer presents itself, if one can make the diagnosis of a varicose extremity by means of the usual diagnostic tests, that the past history of treatment is not of great significance in guiding the future. In other words if injections have been done, ligation is still indicated, and if operative excision has been done it is still likely that there are tributaries bridging the gaps coming down from the sapheno-femoral junction and these tributaries can be secured by high ligation. If ligation has been done it is still possible that the incision may not have been placed at the sapheno-femoral junction or that tributaries were missed at that operation. It is my feeling that if the operation is perfectly done and every tributary secured at the highest level, that the treatment will be permanent, but in view of the "perfect" types of

treatment that have been abandoned in the past, it would be rash to insist on this point. There is no question in my mind, however, but that this method, which has already proved its worth in healing ulcers which have remained open after other types of treatment, is the most efficient method so far advanced.

CHAPEMAN FRENCH The next paper will be given by Dr. George C. Prather. His subject is "X-Ray and Autopsy Study of Anatomical Changes of the Upper Urinary Tract in Patients with Obstructing Prostates."

X RAY AND AUTOPSY STUDY OF ANATOMICAL CHANGES OF THE UPPER URINARY TRACT IN PATIENTS WITH OBSTRUCTING PROSTATES*

BY GEORGE C. PRATHER, M.D. † AND M. L. BRODNY, M.D. ‡

FOR many years "back pressure" has been the usual answer given for poor renal function in patients with obstructing prostates. This simple explanation of upper urinary tract changes has been made either on the basis of (1) incompetency at the ureterovesical junction or (2) on the assumption that the renal pelvis and ureters were working against an increased pressure caused by urinary residual in the bladder.

While it is true that upper urinary tract dilatation has been found many times as a terminal observation in prostatism and forms a "classical picture" we have wondered whether this is a constant relation, if not just how frequently does it occur?

Intravenous pyelography and observations at autopsies, seemed to be available methods for such a clinical study although the former is open to the objection that patients with poor renal functions are not proper candidates for such an

examination. The observations from our small series of cases should be checked by a larger series in order to see if the relations still hold.

Findings in thirty-five prostatitics with intravenous pyelograms were reviewed. In addition, thirty-three cases whose primary cause of death was prostate in origin, were used for our autopsy series.

As to the effectiveness of intravenous pyelograms in patients with prostate obstruction, we may refer to Chart A which summarizes the

findings. In fifty-four per cent the films were satisfactory for an accurate kidney diagnosis, these are classified as good. In twenty-eight per cent of the remainder the films were not good enough for an accurate kidney diagnosis but would permit an opinion as to whether dilatation of the upper urinary tract existed, these are classified as fair. Poor films need no further comment. Therefore, one might assume from this small series that intravenous pyelography would be successful in slightly more than fifty per cent to demonstrate upper urinary tract pathology accurately. To demonstrate the presence or absence of upper urinary tract dilatation there is an eighty-two per cent chance.

As seen in Chart A, the type of prostate appears to make little difference in the chance of success. While one would hesitate to use intravenous pyelograms without discretion in patients with poor renal function, we were able to obtain good or moderately good films in six out of seven patients with n.p.n.'s above forty mg per 100 cc of blood.

There appears to be very little evidence in the literature concerning the frequency of ureteral and kidney dilatation in prostatic obstruction. Thomas¹ in a series of twenty-eight cases coming to autopsy, following relief of prostatic obstruction, found upper urinary tract dilatation in fifteen. The results of our observations on this point are summarized in Charts 1A and 2A. In the series coming to autopsy 35.3 per

cent revealed dilatation of the upper urinary tract in some degree. The pyelographic series showed 17.1 per cent to have dilatation. In each group the average age is higher in the division which shows no dilatation. This is, perhaps, contrary to what one might expect. The

type of prostate appears to have no direct bearing on the question of dilatation. The fact that the pyelographic series shows a higher percentage without dilatation, may be explained by assuming that these cases were less advanced in the course of prostatic obstruction, however, none of these were operated upon in a "prophylactic stage." The average duration of symptoms was somewhat over two years (including those with acute retention), and the average bladder residual was thirteen ounces (including those with acute retention).

We must consider every relation between upper urinary tract dilatation and poor renal function. This combination of conditions has formed the typical picture of the advanced stage of prostatism for many years. All modern texts of urology describe by words and pictures the association of poor renal function with dilatation of the ureters and kidneys in advanced prostatic diseases. We have seen the same picture at autopsy. We are interested in the question of how frequently these findings coexist in the hospital patient with prostatic obstruction.

Is it correct to assume, in a prostatic case with poor functions, that he has upper urinary tract dilatation? Does the patient with an obstructing prostate and upper urinary tract dilatation necessarily have depressed renal function as measured by urological standards?

Certainly we must keep in mind that at the time of life when prostatic obstruction is likely to develop, some chronic kidney pathology may already be established.

Adequate function tests as shown on Charts 1B and 2B, signify a nonprotein nitrogen no higher than 40 mg per 100 cc of blood and a two hour phenolsulphonephthalein test with a reading of at least thirty four per cent.

The above mentioned charts illustrate a very interesting finding which is true in both the pyelographic and antopsy groups. In those which show upper urinary tract dilatation there are more with normal kidney functions than with poor functions. However, cases with no upper urinary tract dilatation do have a higher ratio of good function.

Looking at these observations in the reverse manner it is evident in this small group that there are more cases with depressed renal function showing no upper urinary tract dilatation than those with dilatation. Thomas¹ reported eleven cases with an elevated n.p.n. in his series of twenty-eight antopsies. Only four of the eleven showed upper urinary tract dilatation. He also mentions ten cases in the group showing dilatation of kidneys or ureters in which the n.p.n. was normal.

It therefore, seems unwise to assume that these two conditions (upper urinary tract dilatation and depressed renal function) coexist even in a majority of instances in an average group of hospital patients with prostatic obstruction.

It would be interesting to know the cause of dilatation of the ureters and kidney pelves in certain cases of prostatic obstruction. We do not believe that the correct answer is available at present. Certain explanations have been offered by various writers.

Ureteral reflux seems to occur very infrequently in prostatitis if one judges by cystograms. We have done or seen a large number of cystograms with sodium iodide during the past five years. Reflux has been distinctly uncommon. When it occurs there has usually been a diverticulum near the corresponding ureteral orifice. Physiologists agree that it does not occur in human beings unless the ureteral orifice is injured. Lucas² and Bush and McCradie³ using dogs, found no ureteral reflux with pressures in the bladder up to 180 cm of water (100 mm Hg). Kelly and Burnam⁴ make the statement that "the lower end of the ureter in dogs strongly suggests the arrangement found in man". Graves and Davidoff^{5,6} found ureteral reflux in 27 per cent in their experiments with normal dogs, with an average intravesical pressure of 87 mm. of Hg.

If one dismisses reflux as a factor he may hold to the idea that the ureter has a difficult time projecting urine into a bladder where we assume that the intravesical pressure is high.

This was reviewed by Bush³ in 1923-24 with the following remarks. Campbell⁷ who had observed intravesical pressure in acute retention found a maximum pressure of 80 mm. Hg, withdrawing small amounts of urine markedly reduced the prevailing pressure. Bush also quotes Lucas who has shown that the tonicity of the ureter is not normally overcome until 45 mm Hg pressure (intraureteral) is reached. Marked or long-continued trigonal alterations therefore, would be necessary to produce ureteral dilatation.

Tandler and Zuckerkindl¹⁰ believed that prostatic hypertrophy displaced the vas, allowing it to compress the ureter and produce ureteral dilatation. Falci¹¹ studied sagittal and horizontal sections (gross and microscopic) through the region of the prostate, lower ureter, seminal vesicles and vas and disagrees with that conclusion. He attempted to discover the reason for dilatation in the lower ureter and adjacent tissue without the help of extrinsic pathology.

Young¹² interprets upper urinary tract dilatation in prostatitis as due to frequent and prolonged urination at which time the ureteral orifices are closed. This results in stasis in the ureters at that time interfering with peristalsis. When this is continued over a long period of time a similar effect is produced in the kidney. No clinical or experimental data are given by Young to support this hypothesis. No doubt most urologists have seen patients with large bladder residuals who have been asymptomatic so far as frequency or difficulty with voiding are concerned and who, by intravenous pyelogram have dilatation of the upper urinary tract. Certainly frequent or prolonged urination is not always necessary for the production of upper urinary tract dilatation. As shown in Charts 1C and 2C, there was very little difference in

CHART 1C

average duration of symptoms between those with or without dilatation.

We have seen uninfected cases of prostatism which show marked urinary tract dilatation as

well as many with pyuria in whom there is no dilatation. Certainly infection is not the answer to the cause of upper urinary tract dilatation in prostates, although it may be coexistent.

What factors are responsible for poor renal function in prostates? Undoubtedly the same answer will not hold for all. Poor function sec-

ondary to ureteral and renal dilatation does exist. Superimposed inflammation in the kidney is another factor. Chronic cortical changes due to age or previous renal disease probably exist more frequently than we commonly suppose. Bush⁸ has found that stimulation of the proximal and of the cut hypogastric nerve affects the functional activity of the kidney and that with prostatic changes there is a series of neural reflexes coming from the area of the trigone by way of the hypogastric afferents. This may be completed through the eleventh and twelfth thoracic autonomies to the kidneys. Too little has been demonstrated on an endocrine basis to warrant discussion as a cause of poor kidney function.

We repeat that in our small series, cases with poor renal function showed no upper urinary tract dilatation twice as frequently as those with dilatation.

We wish to express thanks to Doctors W C Quinby and E G Crabtree for the use of material under their control.

SUMMARY

Intravenous pyelography in patients with prostatic obstruction is satisfactory for an accurate upper urinary tract diagnosis in 54 per cent.

The type of prostate makes little difference in quality of pictures.

There is meagre evidence in the literature as to the frequency of upper urinary tract dilatation in prostates.

Our autopsy series shows 35.3 per cent with upper urinary dilatation—the pyelographic series 17.1 per cent with dilatation.

Upper urinary tract dilatation and poor renal function do not coexist in the majority of prostates as seen in hospital.

The cause of upper urinary tract dilatation cannot be explained on any one hypothesis known at present.

In the prostatic, one should not assume that poor renal function is necessarily due to so called "back pressure."

CHAIRMAN FRENCH. The next paper will be given by Dr William C Quinby. His subject is "Some Aspects of the Treatment of Carcinoma of the Bladder."

SOME ASPECTS OF THE TREATMENT OF CARCINOMA OF THE BLADDER*

BY WILLIAM C QUINBY, M D †

BY the use of present-day methods a patient afflicted with a cancer of the urinary bladder can be investigated in great detail and the individual characteristics of the growth evaluated. By microscopic analysis of the urine,

*From the Urological Clinic of the Peter Bent Brigham Hospital Boston Mass.
Read at the Annual Meeting of the Massachusetts Medical Society Section of Surgery June 4 1935.

†Quinby William C—Clinical Professor Genito Urinary Surgery Harvard University Medical School. For record and address of author see This Week's Issue page 499.

blood and pus can be seen. After filling the bladder with a solution opaque to the x-ray a defect in the normal outline of the bladder may be demonstrated. Through the cystoscope the extent and position of the growth, as well as its surface appearance, can be accurately determined. Through the same instrument a portion of the growth can be removed and study of its cellular structure made by the pathologist. But in spite of these and other diagnostic

advantages our efforts to cure patients with vesical cancer still end all too often in failure. Why is this so?

As in malignancy, wherever situated, delay on the part of the patient in asking for medical advice plays a definite part in the number of unfavorable results. But in this especial form of carcinoma this element should not be nearly so prominent as in many other forms. In over sixty per cent of the cases the first symptom is a hematuria, an event which should be sufficiently striking to send the patient to the doctor at once. The medical profession on the whole is acutely aware of the possible seriousness of this symptom, so that only rarely does one now find the doctor to blame for delay in diagnosis and treatment, although this was rather commonly the case in the past. It is therefore, evident that aside from the degree of malignancy of any given tumor, a matter clearly influencing the prognosis but one over which we have no control, the end result depends very largely on the form of treatment instituted once the diagnosis has been made. This is a matter clearly in the hands of the surgeon. It is important, therefore, to review all possible forms of treatment at our command at present, hoping that by a better appreciation of the value and the limitations of each, more patients may be cured.

The methods of treatment from which to make a choice are

1 Closed

- a Deep x ray therapy
- b Fulguration through cystoscope
- c Implantation of radon seeds through cystoscope or application of radium salt.

2 Open

- a Excision
- b Resection
- c Cystectomy
- d Implantation of radon seeds
- e Electrocoagulation (diathermy)
- f Caustic destruction

As in influencing the type of treatment chosen in any single case, several important points in the pathogenesis of bladder tumors in general should always be kept in mind. First, about ninety five per cent of all bladder tumors are epitheliomata, showing a marked tendency to recur, and such recurrences are frequently more malignant than was the original tumor. See only the surface appearance of a tumor may give no accurate information of the extent of invasion of the bladder wall beneath the surrounding mucosa, or into and beyond the muscularis. The cystoscope shows only one side of the growth. Thirdly bladder tumors show a marked tendency to be situated at or near the lower segment of the organ where they cause interference with the trigonal and sphincteric

muscles and with the ureter. About seventy six per cent of all tumors are so situated. Often even a small tumor in this position will be found to have caused extensive renal damage of an obstructive character, all the worse if accompanied by infection. Fourthly, metastases from bladder tumors, either regional or distant, have been found by various recent investigations to be present fairly soon after the onset of symptoms. This, though true, is an unfortunate contradiction of the older idea widely held that, as a whole, bladder tumors were very slow to show metastases. It emphasizes the necessity of early treatment and early operative investigation of the lymph drainage area of the bladder in all but the simplest and most benign cases.

In making a choice of which form of treatment, or combination of forms, best applies to the individual case, judgment must rest on the results of the detailed examination. A small pedunculated growth of papillary type in a portion of the bladder accessible to cystoscopic instrumentation can be easily controlled by endourethral fulguration, or if there is doubt of the relative benignancy of the tumor, after it has been destroyed by the electric current, gold radon seeds may be implanted in the area of the bladder wall from which the tumor arises. Such form of treatment is very successful in those cases to which it is applicable but it must never be overlooked that even the benign papilloma carries potentialities of malignancy, and that treatment even of this type must be followed by careful postoperative observation of the patient's bladder.

In other instances the bladder will be found to contain multiple tumors all of them appearing innocent but occupying various areas, possibly some of them on the anterior wall, a region hard to reach adequately by endourethral instrumentation. Such cases are much more easily controlled through the open bladder. When one has to deal with a growth the base of which cannot be seen or which is of a definitely sessile type the first step in treatment should always be by investigation through the open bladder. In fact there is no doubt in my mind that urologic surgeons have been remiss in being content with the limited attack which closed methods of treatment permit. Too many patients have been treated for too long periods of time by fulguration of their bladder tumors, thus permitting recurrences or unrecognized invasive growth, which later is found to have become inoperable.

It will thus be seen that increasing experience in dealing with bladder carcinomata clearly emphasizes the wisdom of open surgical revision in all cases except the simplest ones. The steps of this operative revision should consist of the following. The bladder should be opened

through a suprapubic approach and the incision in its wall should be so placed as to be well away from the site of origin of any area of neoplasm, a point which has previously been determined by cystoscopy. The tumor or tumors should then be carefully evaluated, (1) as to their character on microscopic examination, (2) as to the degree of involvement of the bladder wall, (3) as to their relation to either ureter or to the bladder outlet. Following this, if any conditions are found on palpation which suggest penetration of the tumor through the bladder wall above its lower segment, this portion of the bladder should be mobilized and the perivesical structures inspected. If the growth seems to be of considerable extent, or if the clinical history indicates that it is of several months' standing the peritoneum should be opened after the bladder has been isolated by gauze packs, and the lymph drainage area as high as the pre-aortic nodes carefully inspected for metastases. The presence of extensive secondary deposits will, of course, contraindicate radical surgical removal and restrict operation to one of palliation only. On the other hand, if only one or two lymph nodes are found involved these can be excised or treated by the implantation of radon seeds.

The present weight of urological opinion as regards the treatment of cancer of the bladder is toward more frequent excision of the tumor by open surgery even though this at times makes necessary the removal of the whole bladder. This trend is without doubt the result of the fact that accumulated experience with other less radical forms of attack has shown them to be too often inadequate. Much was hoped in the earlier days from the use of radium. To day, however, we have learned that though radium properly applied is able to control growths of the lesser degree of malignancy (groups 1 and 2 of Broder's classification) it is ineffective against those of more malignant type. Thus the use of radium alone while of advantage in the less invasive bladder tumors has not been nearly so efficacious in those of higher malignancy. The matter of proper dosage is always somewhat uncertain. The use of the one or one and a half millicurie seeds placed about one cm. apart has considerably simplified this, but judgment is still difficult. If too little is used recurrences will appear, if too much, fistulae may be formed between bladder and rectum or between bladder and vagina. A slough very slow to separate and causing much tenesmus is also rather frequently seen after the use of radium but this is less apt to follow the implantation of gold seeds than when the emanations were used in the older forms less well screened.

Radium seems today to find its greatest use

in the control of the more benign types of vesical carcinoma in which instances it is quite sufficient of itself to produce a cure. In the more malignant varieties it is of much value also when used in addition to some form of surgical excision of the growth.

We will, therefore, employ surgical excision or resection in all cases in which the tumor is so situated that its removal will not interfere with the bladder outlet. Often it will be wise to use radon seeds in the tissues surrounding the area of excision in order to give added assurance.

For those growths situated in the region of the bladder outlet and of high malignancy total ablation of the bladder offers the best outlook for cure. But this is a formidable procedure and not to be employed as a last resort operation. In the patient already cachectic, anemic from loss of blood, and with damaged kidneys and infected urinary tract, only some form of palliation can be offered, no serious attempt to remove the cancer being any longer possible.

A compilation of the results of treatment of cancer of the bladder which have thus far been reported in the literature is hard to make because there has been no standardization. Almost all reports deal with the length of life of the patient after operation either with recurrence or free from it. No account is at hand as to the function of the bladder during such time. An intolerant bladder causing much pain and frequency of urination, interrupting sleep and gradually breaking down the patient's morale may easily follow interference of any sort with those tumors situated in the lower segment of the bladder.

How often this happens does not appear, but it must be frequently. We have here an additional argument in favor of complete removal of the bladder. It may well be that fewer patients will survive this operation but in that case we must remember also that fewer will live wishing that they were dead.

The indications, therefore, for total cystectomy as at present construed are as follows. First, a growth which is of the higher degree of malignancy (groups 3 and 4) situated at the bladder outlet or so close to it or so extensive that bladder function, contraction and relaxation of sphincter and trigone, will be much impaired by its removal. Secondly a patient in good or at least fair general condition. Thirdly, no extensive local or distant metastases to lungs or bones. Fourthly, at least one kidney unobstructed, and of normal function. Under these conditions the patient's best chance is through removal of the entire bladder.

An outline of the steps in cases of cystectomy consists of the following. Two operations are necessary. At the first, surgical revision of the entire situation, as described earlier in this paper, is carried out, followed by the anastomosis

of one ureter to the sigmoid intestine. At the second the remaining ureter is anastomosed if it be normal. If the kidney on this side has been found to be functionless, however, this procedure is not worth while. The ureter should be ligated and severed. Then the bladder is excised, especial care being taken to remove all perivesical fatty tissue and if any areas remain which seem abnormal, into these radon seeds should be implanted.

CONCLUSIONS

1. Carcinoma of the bladder when of the less malignant type and without invasive growth is successfully treated by radium or electrocoagulation. Except in the simplest cases this will best be carried out through the open bladder.

2. Carcinomata of greater malignancy are often resistant to radium and should be resected when situated above the lower bladder segment. Here it may be wise to use radium in addition to the resection.

3. When rapidly growing carcinoma is found to involve the lower segment of the bladder total cystectomy should be performed if the patient's condition is good and no hopeless metastases are present.

4. Open surgical revision of all doubtful cases of bladder carcinoma should be employed much earlier than has been the custom heretofore.

CHAIRMAN FRENCH. The next paper will be given by Dr. David Cheever and is entitled "Methods and Results in the Surgical Treatment of Diseases of the Biliary Passages."

DR. DAVID CHEEVER. Boston. Mr. Chairman and members of the Section when one examines the results of surgical procedures with a view to determining how efficacious they are in the cure of disease I suppose it is very advantageous if a very large number of cases be the subject of inquiry but it has seemed to me that sometimes it may be useful to review a much smaller number of cases and to satisfy one's own personal experience to examine the results. Of course, I think that raises the question as to whether one can be candid in the examination of his own cases and that is a very important question. I assure you that such inquiry is very useful to the individual himself. Whether it is to other people will be a matter for you to determine.

Today I am going to present to you on examination of the cases of biliary tract disease which I have operated on personally at the Peter Bent Brigham Hospital since 1913. That is a period of about twenty-two years.

METHODS AND RESULTS IN THE SURGICAL TREATMENT OF DISEASES OF THE BILIARY PASSAGES*

BY DAVID CHEEVER, M.D.†

A REVIEW of clinical experience in order to secure evidence as to the most satisfactory way to treat illness is doubtless useful in proportion to the number of instances forming the basis of the inquiry. It is possible however that a review of a smaller but not inconsiderable number of cases, whose treatment has been conducted according to a consistent plan, over a considerable number of years, by the same surgeon, may afford useful information, certainly for himself and possibly for others. For this reason I venture to report my purely personal experience in the surgery of the biliary passages, from the date of opening of the Peter Bent Brigham Hospital to the present, a period of about twenty-two years.

The convictions that I reached early and which have formed the foundation of my method of procedure quite consistently ever since, were as follows:

1. There are no such things as harmless gall stones.
2. A gall bladder once inflamed or the seat of calculi, and treated by evacuation and drainage only, is much more likely than a normal gall bladder to be the source of symptoms.

3. The gall bladder, while having a definite physiological function, is a dispensable organ and its removal causes no demonstrable ill effects upon the individual, in the vast majority of cases.

4. In the absence of serious complications the removal of the calculeous gall bladder is in competent hands a very safe procedure. The acutely inflamed or devitalized gall bladder presents a more difficult problem, but one which can usually be solved by the exercise of surgical judgment in the selection of the time and type of operation especially whether it shall be performed in one or two stages.

5. Calculi in the hepatic or common ducts will inevitably sooner or later cause pain, jaundice and cholangitis in varying combinations and degrees, and eventually fatal complications. They may be silent for long periods but are essentially incompatible with health. They occur in a considerable percentage, perhaps twenty per cent of all cases of acute or chronic cholecystitis.

6. No method of diagnosis, whether by history, physical examination, x-rays, laboratory tests or even actual inspection and palpation of the viscera themselves affords cer-

*Read at the Annual Meeting of the Massachusetts Medical Society, Section of Surgery, June 4, 1935.
†Cheever, David—Associate Professor of Surgery, Harvard University Medical School. For record and address of author see "This Week's Issue" page 499.

tain evidence of the presence or absence of calculi in the ducts, negative evidence is especially unreliable in this respect

- 7 Incision, exploration and drainage of the common duct with dilatation of the papilla, afford the only approximately reliable means of diagnosis and relief. They result in no harm to the ducts. While together they constitute a procedure always requiring delicacy and skill, and sometimes extremely difficult, it adds but little to the mortality, if applied with good surgical judgment. Moreover, when indicated, it is absolutely essential that this procedure be carried out if the patient is to be relieved.

With these concepts in mind, it is hardly necessary to say that during these twenty-two years I have, with reasonable consistency, practiced the removal of the acutely or chronically inflamed and the calculus-containing gall bladder, and have explored the common duct whenever there was reasonable suspicion of calculi, provided no forbidding complications existed.

During this period I have made 426 operations on the biliary passages. The technique employed has been so nearly identical and consistent as to furnish, when the results are analyzed, a good basis of comparison with other methods. Deferring for the moment any discussion of the many controversial points in the matter of technique, its chief features may be described as follows:

Anesthesia Ether, by the open mask drop method was used in 362 cases, avertin in basal dose of eighty to ninety mg. with supplementary ether in thirty-one cases, gas-oxygen with novocaine infiltration and supplementary ether when necessary in eighteen cases, gas-oxygen alone in six cases, spinal anesthesia in four cases, various other combinations of these agents in five cases. My present preference is for avertin and supplementary ether.

Incision An incision beginning at the ninth costal cartilage, about two to two and a half cm. to the right of the midline, splitting the right rectus muscle near its medial border, and carried downward, beyond the umbilicus, far enough to give ample room, has invariably been made, the only exceptions being when simultaneous operations have been undertaken, such as partial gastrectomy or splenectomy, requiring a midline or left paramedian incision. I never carry the incision medially into the ensiform angle, dividing thus part of the origin of the rectus and tendon of the linea alba, and I never make a transverse incision, believing that these modifications are unnecessary and present more disadvantages than merits. The incision described has always proved sufficient and presumably does the least damage.

Exploration of the Abdomen A general ab-

dominal exploration is always made first, unless contraindicated by local infection, prevented by adhesions, or made unwise by the patient's general condition. In this connection let me say that much as I approve and practice the manual palpation of all the abdominal viscera, I believe that it may turn the scale against a critical case by favoring postoperative distention and stasis. If the appendix can be brought into the field with reasonable ease and is not atrophic, it is removed, this has been done in the majority of the present series. I am convinced, however, that incidental appendicectomy may be a false ideal. I have seen in consultation a vigorous patient dying of peritonitis after the simplest sort of cholecystectomy with incidental appendicectomy where I believed that some slip in technique related to the difficulty of handling the appendix through an inappropriate incision, was responsible.

Removal of the Gall Bladder After making certain that it may not be necessary for anastomosis, in case a neoplasm be obstructing the common duct, the diseased or calculous gall bladder is removed in one of two ways preferably by laying open the peritoneal sheath of the cystic and common ducts, developing, clamping and dividing the former, securing the cystic artery just above and dissecting the gall bladder from its bed, leaving a peritoneal cuff and following the areolar tissue cleavage plane between the gall bladder and the capsule of the liver, or, if inflammatory edema, infiltration or adhesions makes exact identification of the cystic duct impossible or even difficult, the attempt is ceased and the dissection is begun at the fundus of the gall bladder, finally developing the artery and especially the cystic duct as an ultimate pedicle, about which no doubt exists. This method is somewhat bloody and it may hurt the operator's pride, but it is safe. It has been used in about one-third of the cases in this series. I have never regretted using it. The cystic artery and duct are transfixed and tied, usually separately, with double zero chromic catgut. No 1 gut makes actually a less safe ligature on such small soft structures. I have not had, to my knowledge, postoperative hemorrhage from the cystic artery.

Exploration of the Duct The free edge of the gastrohepatic omentum is split and the peritoneum reflected, exposing the duct, and permitting rough determination as to whether it is dilated. Palpation is carried out with the forefinger of the left hand in the epiploic foramen and the thumb anterior to the duct, hepatic artery and portal vein, all of which structures are thus palpated in their supra-duodenal portions, the retro-duodenal part of the duct is exposed by mobilizing the second portion of the duodenum to the left and the duct palpated in the enfolding substance of the head of the pancreas. If the indication exists, the duct is

opened by anterior longitudinal incision below the confluence of the cystic duct, and exploration carried out, first by a small scoop with mal-leable shank, secondly by graduated olive-tipped urethral bougies, whose successful passage through the papilla into the duodenum is proved by the irrigation test. The hepatic ducts are explored in a similar way. If calculi or detritus are present, the papilla is dilated by the passage of graduated bougies, as described in a previous paper. If the pathologically dilated stump of the cystic duct invites exploration through its lumen rather than through an incision in the common duct, this avenue is used but in my experience it is rarely so satisfactory and offers more disadvantages than otherwise over the former method. Drainage is nearly invariably carried out by an inlying rubber tube of suitable calibre, with a terminal opening and a lateral fenestration about two cm. proximal to the end passed upward with the intention that the end may pass into either primary hepatic duct and the lateral opening may be opposite their confluence, thus giving unobstructed drainage of bile.

Drainage of the Wound In the earlier cases in this series, the field was invariably drained by a small soft rubber or protective tissue egnette drain, with no gauze tampon, carried down to the deepest part of the subhepatic fossa and brought out at the upper angle of the wound. More lately, if the field is clean and dry, no drain has been used. Usually when an inlying tube has been placed in the common duct it is considered to be a sufficient drain for the whole field. I do not use drainage through a dependent lateral incision, believing that it has no compensatory advantages.

Wound Closure has been almost invariably by continuous No. 1 chromic catgut to the peritoneum and posterior sheath, overlapping interrupted mattress sutures of No. 1 or No. 2 chromic gut to the anterior sheath with or without supporting sutures of silk worm gut through all layers but the peritoneum. Since these wounds are never surgically clean, and as I am convinced that even sterile bile is a deterrent to sound healing, and since postoperative disruption and hernia are not uncommon in these wounds, it seems wise usually to use supporting sutures.

Postoperative Care has been conducted according to prevailing principles. I have always deprecated the application of tight bandages as tending to diminish vital capacity and to create conditions favorable to pulmonary congestion, atelectasis and pneumonia. On the other hand I believe that fairly firm support for the lower part of the wound is advisable for the comfort which it gives and for security. Morphine in small doses is necessary to afford rest, lessen nervous wear and tear and aid pulmonary expansion by limiting pain. Ventila-

tion by CO₂ seems to be useful, but I am not certain.

The results of these concepts and principles of treatment are now presented. Table II shows

TABLE I

that the total operative hospital mortality in 426 operations on the biliary tract (excluding carcinoma) was 3.2 per cent. A statement of the greatest, least and average age, of the proportion of sexes and of the average postoperative days in the hospital is given.

TABLE II
PERSONAL CASES PETER BENT BRIGHAM HOSPITAL
1913-1935

416 Patients had 426 Operations on the biliary passages exclusive of carcinoma.
There were 14 deaths a mortality of 3.2%
Oldest—83 years
Youngest—14 years
Males—80
Females—336
Average postoperative days in Hospital—19.4%

Table III gives the number of various pathological conditions the types of operations performed, and the mortality of each group. Here certain explanations must be made. Instances reported by pathological examination as "subacute cholecystitis" have been classified as acute. The term "subacute" seems to me not useful or exact. Similarly, in a few instances in which a pathological diagnosis of chronic cholecystitis is recorded, but which were characterized clinically by marked fever, leucocytosis, local tenderness and spasm, and by operative findings of a swollen, congested, edematous, mottled or even semi-necrotic gall bladder containing puriform fluid, the disease has been recorded as acute. Whether this classification finds acceptance the fact may be pointed out that taking together all the cases of cholecystostomy and simple cholecystectomy for acute cholecystitis of all degrees, together with the cases of secondary cholecystectomy following prior cholecystostomy, we have ninety-three operations concerned with acute cholecystitis carried to a final conclusion without mortality. On the other hand, the evil influence of acute cholangitis and

calculi in the common duct requiring exploration of the latter, as a complication of acute cholecystitis, is seen in the twenty-one instances of cholecystostomy and primary cholecystectomy each with exploration and drainage of the common duct, which show three deaths, a mortality of 14.2 per cent. Similarly, the contrast of a mortality of 1.1 per cent in 169 instances of primary cholecystectomy for chronic cholecystitis, and of a mortality of 3.2 per cent in 123 instances of primary cholecystectomy for chronic cholecystitis with drainage of the duct,

TABLE III
TOTAL BILIARY TRACT OPERATIONS

	Cases	Deaths	Mortality %
Cholecystostomy, alone, acute and chronic	17	0	0
Cholecystostomy and Drainage of Common Duct	5	1	20
Primary Cholecystectomy for acute cholecystitis	45	0	0
Primary Cholecystectomy for acute cholecystitis with Drainage of Common Duct	16	2	12.5
Primary Cholecystectomy, only, for chronic cholecystitis, with or without calculi	169	2	1.1
Secondary Cholecystectomy following Cholecystostomy	31	0	0
Primary Cholecystectomy for chronic cholecystitis, with Drainage of Common Duct	123	4	3.2
Drainage of Common Duct, alone, chiefly secondary, after operation here or elsewhere	12	1	8.5
Miscellaneous, including drainage of peritonitis and sepsis from spontaneous rupture of biliary passages, etc, including one cholecystectomy for acute yellow atrophy	8	4	50
	426	14	3.2%

Or, take 1, 2, 3, 4 and 6 together—mortality of 2.6%

shows the serious factor introduced by common duct disease into the surgery of the biliary system. The four deaths listed under "miscellaneous" should be further examined. The first concerned a secondary exploration of a complete biliary fistula, following drainage of a biliary and septic local peritonitis due to spontaneous rupture of the bile duct subsequent to cholecystectomy and failure to explore the duct, performed elsewhere. Autopsy showed peritonitis, multiple abscesses and arteriosclerotic kidneys. The second was an acutely ill woman whose gall bladder had been removed elsewhere two years previously. A right-sided biliary and purulent peritonitis was drained, and three weeks later exploration showed a spontaneous perforation of the retro-duodenal part of the duct,

with calculus. An anastomosis was attempted, death occurred in eighteen hours. Autopsy showed peritonitis, cholangitis, hepatitis and multiple abscesses. The third was a woman of sixty-eight with jaundice due to a stricture of the duct following operative injury two years previously. At operation a transduodenal approach was necessary to identify the duct, a reconstruction of the duct was done, death occurred on the eighth day, the autopsy showed peritonitis apparently due to a weakening of the duodenal wall occasioned by the separation of adhesions. The fourth case was a jaundiced woman complaining of epigastric pain, an adherent but otherwise normal gall bladder was removed (reported normal by the pathologist) and the duct opened with negative findings. The liver was small and soft, acute yellow atrophy was suspected, death occurred with toxic symptoms in thirty hours, autopsy showed that lesion to be the cause of death. This case was not included in table II under "Primary Cholecystectomy for Chronic Cholecystitis, with Drainage of Common Duct" because it did not seem to belong there, if it is included it will raise the mortality in that group from 3.2 per cent to 4 per cent.

Table IV indicates the number of times the

TABLE IV
426 OPERATIONS ON THE BILIARY PASSAGES,
PERSONAL CASES, PETER BENT BRIGHAM HOSPITAL
1913-1935

The Common Duct was explored in 37.9% of 426 operations on the Biliary Passages, as follows:

Primary Cholecystectomy for acute cholecystitis	16
Cholecystectomy for chronic cholecystitis	123
Primary and Secondary Choledochostomy only	15
Primary Cholecystostomy	4
	158

Calculi were found in 70 cases, or 44.3% of instances of exploration of the Common Duct.

(Note—"Calculous débris," 9 cases, are classified with calculi.)

common duct was explored in certain types of cases, and the incidence of calculi. It was hard to know how to classify "calculous débris or detritus", it seemed fairest to classify them under calculi, with this word of explanation. This table shows that the common duct was explored in 37.9 per cent of all operations on the biliary tract, and that calculi were found in 44.3 per cent of those explored, or in 16.4 per cent of the total number. This proportion has remained fairly constant in my hands, because I was early convinced of the necessity and comparative harmlessness of opening the duct.

Table V lists the postoperative complications, excluding those in fatal cases which will be separately considered. The problem here is to distinguish between the various frequent and usual

sequelae of major abdominal operations which are so common and inevitable as to be expected in the average case, and those which are marked or severe enough to modify the course of convalescence or require special measures for their alleviation. There were twenty six instances of respiratory complications of which seven are listed as pneumonia, usually on the basis of roentgenological rather than physical evidence. Atelectasis is not listed since only minor degrees of the condition were noted which are included under the captions "pneumonia" or

Persistent Vomiting	1

"minor respiratory" The six wound infections include cases where it was necessary to re-open and drain a considerable part of the wound for cellulitis. Naturally, very many of these wounds are slightly infected. In six instances there was some separation of the fascial and muscular layers, requiring either re-suture or firm strapping. In no case was there disruption with evisceration. Of the two cases of hemorrhage one was a slow leakage from the gall bladder bed in the liver requiring re-opening of the wound and suture, the other was a minor oozing from a vessel in the rectus sheath. The two pulmonary infarctions were of comparatively minor type. The two instances of secondary late discharge of bile represented accumulations after the withdrawal of the drainage tube, and were of no consequence. There was no instance of persistent biliary fistula.

The question of the performance of other operative procedures during the course of operations on the biliary tract often arises and must be settled on the question of the urgency of the associated lesion and the probable ability of the patient to withstand the double strain. In very many instances, operations of pure expediency which could doubtless perfectly well be postponed to a later date can be performed with safety, to the great satisfaction of both doctor and patient. In the present series, nineteen simultaneous operations of some importance have

been performed with one death. This was in a cachectic, jaundiced woman with a history of gastric ulcer for years. There was marked gastric atasis. At operation a cholecystectomy for chronic cholecystitis and gall stones was done, the largest calculus of my experience removed from the common duct, and a Finney pyloroplasty made for the relief of pyloric obstruction. Death occurred in five days, no autopsy. It was my judgment that correction of all the lesions at one time was necessary for recovery, but perhaps a two-stage operation could have been carried out successfully. The list of the eighteen successful multiple procedures is as follows:

Cholecystectomy, removal of pancreatic cyst
Cholecystectomy, sleeve resection of the stomach for ulcer
Cholecystectomy, sleeve resection of the stomach for ulcer
Cholecystectomy, Finney pyloroplasty
Cholecystectomy, posterior gastro-jejunostomy
Cholecystectomy and choledochostomy, gastro-jejunostomy
Cholecystectomy, repair of old ventral hernia, three cases
Cholecystectomy, removal of ovarian cyst, two cases
Cholecystectomy, choledochostomy, removal of ovarian cyst
Cholecystectomy, choledochostomy, splenectomy, three cases
Cholecystectomy, ventral suspension of the uterus
Cholecystectomy, ventral suspension, anterior colporrhaphy
Cholecystectomy total mastectomy

PERSONAL CASES BILIARY TRACT DISEASE
PETER BENT BRIGHAM HOSPITAL
1913-1935

20 Cases of Simultaneous Unrelated Operations

Resection of the stomach for peptic ulcer	2
Finney Pyloroplasty for peptic ulcer	3
Posterior Gastrojejunostomy for peptic ulcer	2
Removal of pelvic tumors	3
Suspension of the uterus	2
Repair of Old Ventral Hernia	3
Splenectomy for Various Types of Splenomegaly	3
Misceellaneous	3

There was one death, a case of cholecystectomy exploration of the common duct and Finney pyloroplasty for obstructing ulcer.

Cholecystectomy, choledochostomy and splenectomy simultaneously performed in three patients make a group of some interest. The first was a jaundiced markedly anemic man of thirty-six, studied on the medical service, where a diagnosis of splenomegaly, cholelithiasis and perni-

cious anemia was made. The history was of recurring attacks of long continued jaundice over a period of two years, with vomiting, weakness, loss of weight and anemia. There was doubt as to whether the jaundice might be hemolytic in type. At operation under ether, through a midline incision, a spleen twice normal size was removed, the gall bladder containing many small calculi excised, the duct explored with negative result and drained. The patient made a good operative recovery, was treated for pernicious anemia, and died two years later (before the days of liver therapy). The second patient was a markedly anemic, jaundiced woman of twenty-eight with a spleen whose lower pole was below the umbilicus and across the midline. There were definite attacks of biliary colic. At operation under ether anesthesia, a left paramedian incision was made, the very large adherent spleen removed, a small contracted gall bladder containing a soft calculus and buried in adhesions, excised, and a considerably dilated duct explored with negative findings. In spite of a red count of 2,800,000 no transfusion was necessary, the patient made an excellent recovery and reported herself as perfectly well eighteen months later. The third patient was a thirty-eight year old jaundiced woman with compensated double mitral disease, marked splenomegaly and moderate anemia. There was little complaint of gall stone symptomatology, but x-rays showed suggestive shadows. Under ether anesthesia, through a left paramedian incision a spleen of three times normal size was removed, the gall bladder containing calculi excised, and the common duct opened and relieved of several small calculi. She made an excellent recovery, and eight months after the operation was delivered of a ten pound boy, so that it appears that she may have been pregnant at the time of operation. The ducts were opened in these cases with little evidence of the presence of possible calculi, because it was determined to clear up the responsibility for the jaundice. In only one case were calculi found, and it seems unlikely that they were responsible, although to leave them would have invited further trouble.

Table VII presents the end-results in this series so far as known at present. They are taken from the Hospital records and represent the gleanings from the regular two-year follow-up system, supplemented in many instances, especially private patients, by reports covering many years. They confirm the impression which all surgeons have that the results of surgery on the biliary passages are extremely satisfactory. As is usually the case, it is easy to find explanations and excuses for many in the "not relieved" column. Two patients from whom gall bladders containing calculi were removed (normal common duct),—proved to be psychotic, continued

their food strikes, and died months afterward from inanition without biliary tract symptoms, three patients with non-calculous chronically inflamed gall bladders got little relief from their removal, as is well known frequently to be the case, two patients were re-operated on later and previously overlooked common duct calculi removed, in two patients the symptoms strongly

suggested overlooked calculi but for various reasons no re-operation was done, five patients who were operated on for organic biliary tract disease, subsequent events proved to be suffering also from other abdominal visceral conditions.

A statement of the causes of death in the fourteen fatal cases appropriately closes the statistical part of this report, as follows:

Hemorrhage—1
Myocarditis and renal insufficiency—2
Shock—1
Myocarditis and asthma—1
Angina pectoris—1
Pulmonary embolism—1
Peritonitis—2
Sepsis, cholangitis—2
Cholemia, uremia, hepatic insufficiency—1
Acute yellow atrophy—1
Unexplained—1

The single known death from hemorrhage was most interesting on account of its unusual cause. It concerned a forty-eight year old jaundiced man with an icteric index of fifty to seventy-nine, a bleeding time of two minutes and clotting time of two minutes, forty-five seconds. A tensely distended adherent gall bladder full of calculi and a huge common duct containing

fourteen of the largest calculi in my experience created some difficulties but the usual technique was carried out including closure of the gall bladder fossa with sutures of 00 chromic gut, the field was left dry and the patient came off the table in supposedly fair condition. Four hours later he was suddenly noted to be shocked, and death occurred seven hours after operation. There was no bleeding from the drainage tract. A very careful autopsy showed that an anomalous right hepatic artery derived from the superior mesenteric entered the liver and ran for some distance just beneath the capsule of Glisson in the liver bed, it had been pricked by the needle in closing the latter and had leaked into the peritoneal cavity. The instance

of unexplained death was an easy cholecystectomy for chronic cholecystitis and cholelithiasis in a thirty-seven year old woman, not jaundiced. She came out of her ether anesthesia, talked, and was thought to be in satisfactory condition. Seven hours after operation she rather suddenly became weak, restless, anxious and sweaty. Examination of the drainage tract showed no evidence of hemorrhage so she was not transfused, and other measures failed to prevent her death eleven hours after operation. Autopsy was refused, but again examination through the wound showed no bleeding. The cause of death remains a mystery, it may have been embolism, but no pulmonary pathological condition was noted.

I am frankly puzzled as to the existence of a somewhat mysterious "liver death", as described by Heyd and discussed by others to which persons operated on for biliary tract disease are peculiarly liable to succumb. This is supposed to be of three types—first, a patient with simple cholecystitis without jaundice, fails to recover consciousness or lapses at once into coma, the pulse rate and temperature rise rapidly and death occurs in thirty-six hours, secondly, a patient on whom a choledochostomy is done for obstructive jaundice who progresses favorably for a few days and then develops successively excitement, delirium, stupor and coma while the bile becomes less in amount

and more watery in character, thirdly, a patient with cholangitis and pancreatic disease but without jaundice progresses well for twenty-four hours only to lapse into a condition resembling a delayed shock with falling blood pressure, cold extremities, urinary suppression and death. It does not appear that any of the deaths in this series conform to these groups, and since the observed lesions in most of the fourteen fatalities among 426 operations on the biliary passages amply account for the issue, scarcely anything seems to remain to be puzzled about. Perhaps S. No. 10527 is an example of the second type. He was a man aged twenty-four, upon whom five and a half months previously a cholecystectomy for chronic cholecystitis and cholelithiasis had been done, the duct having been explored with failure to secure a calculus which slipped up into the hepatic ducts. He was well for five and a half months and then was readmitted with epigastric pain, jaundice and clay-colored stools of eleven days' duration. At operation the common duct was explored in the usual manner, with failure of instrumental passage through the papilla; the duodenum was mobilized and the ampulla of Vater opened through the edge of the pancreas and a calculus removed. There followed profuse discharge of bile and a breaking down of the wound suggesting the agency of pancreatic secretion, though of this there was no real evidence and the wound granulated well. Biliary discharge continued, and some bile appeared in the stools, but the patient vomited occasionally, became unreasonable and morose, insisting on smoking and getting out of bed. The abdomen remained soft and not distended; the bowels moved satisfactorily and there was no fever. He died of exhaustion on the twentieth day; no autopsy could be obtained. This occurred sixteen years ago and some of the measures and laboratory work which would be routine now do not appear upon the records. Perhaps this was a "liver death", but to my mind there was no more evidence of liver insufficiency than of other visceral failure.

Adequate liver function is necessary for life, and if degeneration of liver parenchyma occurs from any cause to a degree reducing its functional efficiency below a certain level, death will ensue. Such a degeneration occurs as a part of the pathological picture in numerous diseases. Inasmuch as gall stone disease is so commonly associated with jaundice and cholangitis, conditions which have a directly harmful effect on the liver cells, which may be suffering also from blood borne toxins and poisons, it is only reasonable to believe that diseases of the biliary tract must be peculiarly liable to a fatal issue due to hepatic insufficiency. That over and above this there is a peculiar type of "liver death" I am extremely skeptical if there is, it seems remarkable that no definite

instance has appeared in this series of 426 operations

Some years ago I called attention to the practice of purposeful dilatation of the papilla of Vater in the course of exploration, evacuation and drainage of the bile duct, to favor more free natural drainage and the passage of overlooked calculi and débris into the duodenum. Objection has been raised to this on various grounds, but chiefly on account of the obvious possibility of the reflux of activated pancreatic enzymes and duodenal contents with consequent digestion of the wound and duodenal fistula, well known to be a very fatal complication. It is timely now to state that I have carried out this procedure consistently, when possible, in every case of common duct exploration without experiencing a single clear instance of unfortunate sequelae. The one instance where duodenal and pancreatic reflux was suspected, was in the case noted above where the ampulla had to be opened by retro-duodenal approach, affording ample opportunity for direct leakage. An important paper by Allen and Wallace on this subject, from the Massachusetts General Hospital, soon to appear, is strongly confirmatory of this point of view. I am convinced that the relative freedom of the patients in this series from symptoms of persistent or recurrent calculi in the ducts is in some measure due to dilatation of the papilla.

One of the underlying concepts mentioned at the beginning of this paper was that surgical deprivation of the gall bladder, in the vast majority of cases, caused no digestive disturbances or had other regrettable sequelae, and the end results in this series seem fully to justify this belief. The ill effect most frequently attributed to cholecystectomy is diarrhea, alleged to be due to the constant pouring of unconcentrated bile into the duodenum, when it is not actually needed for digestion. The firmly held belief of some internists in this result has led

me to make particular inquiry about it. In the 325 patients with a follow-up record, there is mention of diarrhea in just one instance, and in that it was a feature of chronic intestinal indigestion long prior to the operation. Particular personal inquiries among private patients have never brought a complaint about diarrhea, and I believe that as a sequel to cholecystectomy it is a myth.

Such a communication as this could not end without the usual plea that patients with disease of the biliary passages be brought to the surgeon early rather than late. No surgeon claims that his art is preferable, if more natural and equally effective means of cure are at hand. Unfortunate incidents and results may attend surgery. In this series, in two instances there was serious operative injury to the ducts, successfully repaired for the time, at least, and there are seven known cases of postoperative hernia. But almost uniformly the unfortunate incidents are in neglected cases, where operative risks are greatly enhanced by complications. It is the old story, education of the profession and the public to a realization of the evils of delay will place the surgery of the biliary system in the same category of efficiency and safety as appendicitis.

CHAIRMAN FRENCH: The next paper will be read by Dr. Fuller Albright. His paper is "Hyperparathyroidism."*

*The paper by Dr. Albright is being retained until further studies on the subject have been completed.

CHAIRMAN FRENCH: The Nominating Committee has brought in for you two names for officers of this Section for next year. For Chairman, Dr. E. P. Hayden, Boston, and for Secretary, Dr. Frederick S. Hopkins of Springfield. Are there any other nominations? If not, I will ask for an expression of your opinion. All those in favor of these two names will say Aye, those opposed No, so voted.

The next paper will be read by Dr. Oliver Cope. Its title is "The Surgery of Subtotal Parathyroidectomy."

THE SURGERY OF SUBTOTAL PARATHYROIDECTOMY*

BY OLIVER COPE, M.D.†

1. INTRODUCTION

HYPERPARATHYROIDISM can no longer be considered a rare disease. Since the surgery of the parathyroid glands is in so many respects unique in the field of endocrine surgery, the problems of treatment of hyperparathyroidism merit separate consideration.

At the Massachusetts General Hospital there have been twenty-seven cases of proved hyperparathyroidism. Eleven of these have been re-

*From the Surgical Services of the Massachusetts General Hospital.

Read at the Annual Meeting of the Massachusetts Medical Society, Section of Surgery, June 4, 1935.

†Cope, Oliver—Assistant in Surgery, Massachusetts General Hospital. For record and address of author see This Week's Issue, page 499.

ferred from clinics near Boston where several of the doctors have taken an active part in the study of this disease. Through the imagination and unceasing interest of Dr. Albright and the active cooperation of the entire staff of many departments, sixteen of the cases have been found in our hospital clinics. It is thus apparent that this large series of cases has not been collected from far afield, but that a considerable proportion have been found in the routine run of patients appearing at the Massachusetts General Hospital. In order to facilitate the investigation of the problems of parathyroid surgery, the Surgical Staff assigned to Dr. Churchill the surgical management of these

cases. This assignment Dr Churchill has very generously allowed me to share with him and I am indebted to him and to the Surgical Staff for being able to report this work.

Dr Albright has discussed aspects of the diagnosis of hyperparathyroidism. I shall therefore, not concern myself with the difficulties and problems of diagnosis but shall limit this paper to the treatment of the disease.

The treatment of hyperparathyroidism may be divided into three parts. The first or medical treatment, as the result of the experience of our early cases, is now known to be dangerous. Of the three patients in this series who have subsequently died, death can be directly attributed to the renal complications of the disease. In two of these three patients although prior to operation clinical improvement was obtained with a high calcium diet, deposition of calcium phosphate occurred in the kidney during the period of observation. Two of the three deaths were primarily due to the impairment of renal function, the third to abscesses in both kidneys following the removal of a stone from one.

The second possible form of treatment is by radiation. We have tried this, are trying it at the present time, and so far have been unable to demonstrate any success. The reports in the literature of benefit by x-ray treatment in hyperparathyroidism unfortunately cannot be accepted since the data furnished are insufficient for proper evaluation.

Surgery is then left as the third and recommended form of treatment, although the ultimate success remains to be determined as time advances. To date the results have been excellent in the group of single tumor cases with out severe renal complications. In those cases with generalized hyperplasia of all parathyroid glands, the result of operation is not yet established although immediate improvement occurs.

2. DISSIMILARITY TO THYROID SURGERY

The surgery of the parathyroid glands is based upon the same principles as the surgery of any endocrine gland. It involves the removal of overfunctioning parathyroid tissue. If potentially normal functioning parathyroid glands are present, the surgery is limited to the removal of one or more adenomatous glands. If all of the parathyroid tissue present is overactive, sufficient of this tissue must be removed so that the remaining hyperactive tissue brings the parathyroid activity within normal limits. In this sense it is similar to the surgery of the thyroid, adrenal, pancreas or other endocrine gland.

In the case of the thyroid gland, the surgical treatment has reached a high plane. The indications for operation are becoming daily clearer. The surgical technique has been fully demonstrated and the pitfalls carefully described by a large number of workers. There

are two things which have aided the accomplishment of this. First, the thyroid gland is anatomically accessible. Secondly, if too much thyroid tissue is removed in the operation so that the thyroid activity is brought below normal requirements a replacement therapy is readily available. A patient in whom partial myxedema is produced by over zealous removal of thyroid tissue may not thank you for condemning him to take dried thyroid or thyroxin but at least his life has not been endangered. In hypothyroidism thyroid medication produces normal health. Thyroid extract is an adequate replacement therapy.

In the case of the parathyroid glands, however, there is no such adequate replacement therapy. The use of parathormone in hypoparathyroidism or tetany of parathyroid origin is not comparable to the use of thyroid in myxedema. The parathyroid hormone as it is available at present does not have a constant effect. A so-called immunity develops following its administration which in a short time prevents its constant use in large doses over a long period of time. In mild tetany calcium by mouth may be adequate to control the symptoms. In severe tetany, Viosterol in relatively large doses is the drug from which most benefit can be derived. Let me emphasize, however, that the removal of too much parathyroid tissue may condemn the patient not only to tetany, its disagreeable neurological symptoms and to cataract but also if the tetany is severe, to a possible fetal outcome. In two of our patients who died, tetany was a contributing cause of death.

The treatment of chronic tetany by grafts of parathyroid tissue is still in the experimental stage. The reports of Stone and others of the success of human parathyroid grafts remain to be established. Stone's method of grafts spans in one step, at least, three major biological difficulties of tissue culture and grafting. Much work must be done before these reports can be accepted.

Surgery of the parathyroid glands involves naturally many of the same anatomical considerations common to thyroid surgery. The identification of parathyroid tissue is, however, so much more difficult, that although the anatomical considerations may be the same the surgical technique must be considerably different. In our series of twenty-seven cases, there are four patients who were operated upon previously by other hands without exposing the parathyroid tumor. At a subsequent operation at the Massachusetts General Hospital, a tumor was found in each case. It has become apparent that the previous failures were due to an attempt to apply the technique of thyroid surgery to the problem of the parathyroid glands.

The search for parathyroid tissue must be carried to far greater distances than the area immediately surrounding the thyroid gland. It has been found that the parathyroid bodies may

occur over a wide area. The embryological descent of parathyroid tissue from the pharynx into the neck determines this area. In this series parathyroid glands have been found from above the level of the upper poles of the thyroid to the second interspace in the anterior mediastinum and also in the posterior mediastinum. Theoretically they may occur from the pharynx down to the lowest expected level of thymus tissue.

The recognition of parathyroid tissue even when exposed may be difficult. Great care must be taken to avoid traumatizing the parathyroid tissue which has no supporting stroma similar to that of the thyroid. The slightest trauma causes the rapid spread of hematomata in the parathyroid tissue which destroys the characteristic light brown color with the smooth glistening surface changing it to a redder, rougher tissue, easily mistaken for normal thyroid or a hemolymph gland. In one of our recent patients, I spent over an hour finding the fourth parathyroid gland because in the original exposure of the left thyroid lobe I had traumatized the only exposed portion of this gland as it lay in the sulcus of the thyroid lobe. It was necessary to search every other possible location for this gland before opening into the thyroid gland. Complete exposure of it proved it to be a tumor almost completely buried in the thyroid.

Every surgeon versed in thyroid surgery realizes the difficulty of recognizing parathyroid tissue. It is one thing, however, to avoid the removal of parathyroid tissue in performing a thyroidectomy and quite another to expose and identify all of the parathyroid tissue present. From the technical point of view this cannot be too strongly emphasized. The surgical method ordinarily applicable to thyroid surgery may be inadequate or insufficient when applied to the parathyroid glands. Infinite care, a bloodless technique, time and patience are required to solve satisfactorily the problems of parathyroid surgery.

3 HYPERPARATHYROIDISM ASSOCIATED WITH ADENOMAS

All the operative cases of hyperparathyroidism reported in the literature, other than those from our clinic, have been associated with distinctly localized adenomas of one or rarely two parathyroid glands. Hyperfunctioning adenomatous tissue is the common cause of the disease. Twenty-one of our cases fall in this group. The treatment in these cases once the adenomas have been isolated is either total or subtotal removal. In the majority of cases the whole adenoma is excised. If two adenomas are found, both will be removed.

On the other hand there are, we believe, definite indications for a subtotal removal of these parathyroid adenomas. If a previous operation

has been performed, in an attempt to find a tumor, two things may have occurred which will alter subsequent procedure. If the surgeon was not familiar with the appearance of normal parathyroid tissue he may have removed one or more normal parathyroids thinking they might be tumors. This occurred in all of the four cases which had been operated upon elsewhere. This is an unwise procedure since it does nothing to cure the disease and only jeopardizes the patient's life when the tumor is finally found. In addition, rough handling of normal parathyroid glands or their vascular pedicles with consequent scar tissue formation and impaired blood supply may reduce the amount of available normal parathyroid tissue. Either or both of these conditions are definite indications for subtotal removal of the parathyroid tumor when it is found at a secondary operation.

The third indication for subtotal removal of a parathyroid adenoma is active bone disease with a preoperative high blood phosphatase value. The blood phosphatase, I believe, is an indication of the rapidity of resorption and deposition of calcium phosphate in the bones. The drop in blood calcium following an operation is apparently to a certain degree carried into tetanic levels by bones hungry for calcium. It has thus become our plan to leave a portion of a single tumor when a previous operation has been performed and we cannot be certain of the amount of remaining normal parathyroid tissue or in the case of patients with active bone disease with high phosphatase levels.

It is unfortunate that the size of the tumor may give an erroneous indication of the degree of hyperactivity. The largest tumor of the series weighed 53.2 grams and measured 6.5 by 5 by 3.5 centimeters and was unaccompanied by tetany following the removal of the whole tumor. The smallest tumor which measured 10 by 5 by 4 millimeters, very little larger than a normal gland, was accompanied by marked osteoporosis, severe skeletal changes with incapacitating spine deformities. The removal of this small tumor has presented perhaps the most dramatic cure of our series. Before this patient was operated upon in January, 1932, she had been practically bedridden for two years. Six months after operation she was up and about, well, and looking for work. To the present time she has remained cured.

In our series of twenty-one cases of parathyroid adenomas, subtotal removal has been carried out in seven. Four of these were in patients who had had previous operations and two of these have subsequently died, one died six weeks after operation from renal insufficiency and tetany, the other two years after operation from kidney infection. The third remains well after two and one-half years. The fourth has been operated upon only recently.

Of the three who had had no previous operation, two are well with normal parathyroid function for over a year, the third had the remainder of her tumor removed in a second operation which has resulted in complete relief of her symptoms for more than a year and a half. We believe that subtotal removal should be done recognizing that at a later operation it may be necessary to remove the remainder of the adenoma. It is much better to have to perform a second or third operation than to subject the patient to the tortures of tetany or to possible death.

I should also like to point out that tetany is increased by sepsis or other infections. The presence of infection may therefore be another indication for subtotal parathyroidectomy.

4 HYPERPARATHYROIDISM ASSOCIATED WITH HYPERPLASIA OF ALL PARATHYROID TISSUE

One year ago Drs. Albright, Churchill and Castleman reported from our clinic three cases of hyperparathyroidism associated with hyperplasia of all the parathyroid glands. Each of the glands in its entirety showed a similar type of hyperplastic tissue microscopically distinct from the adenomas. Since that time Dr. Churchill has operated on one more case and I have had two cases. The occurrence of these six cases in our series of twenty-seven which is in the approximate ratio of one to five is so significant that they warrant special consideration. In other words in cases of hyperparathyroidism more than one in every five cases may be expected to be of this type. Clinically we have found nothing to differentiate these cases and the adenoma group. The surgeon who attempts operation upon a patient with hyperparathyroidism must be prepared not only to uncover and recognize a parathyroid adenoma but also to differentiate hyperplastic tissue and if this is present to uncover all the parathyroid tissue.

This diffuse hyperplasia of all the parathyroid tissue is transforming the surgical problem of hyperparathyroidism from mainly a "hide-and-go-seek" game to one of considerably greater difficulty. Subtotal parathyroidectomy must be the rule in all these cases and since no normal parathyroid tissue is present, the difficulty of determining how much tissue to leave behind is greatly enhanced. It should be pointed out that until a safe replacement therapy is available we are not sure that in these cases surgery will prove to be the best method of treatment.

I should like to present briefly the history of two of these six patients.

The first is a man of thirty-nine years whose symptomatology was mainly directed to his renal complication. He had had a series of attacks of renal colic which sent him to our hospital for study. He had also had for two years a mild generalized weakness. Investigation showed an elevated blood calcium, lowered blood phosphorus and a normal

blood phosphatase. X-rays of the entire skeleton showed no obvious bone disease. On exploring his neck, a parathyroid tumor was uncovered on the right side which from previous experience was recognized grossly as hyperplasia. It was more irregular and of a darker brown hue than adenomatous tissue. Further exploration revealed enlargement of all four parathyroid glands. It was in this case that nearly half the operative time was spent finding the fourth gland. To have been satisfied with three tumors would have done the patient no good. The finding of hyperplasia in one gland necessitates the uncovering of all the parathyroid tissue in order to evaluate how much gland is to be left and how much to be resected. Great care must be used in exposing the tissue since it is necessary to preserve the blood supply intact and to avoid the formation of hematomata in the portion of the tissue which you may want to leave behind.

After all four glands had been isolated and the position of the delicate pedicles determined, three in toto and all but a small portion of the fourth were resected. The unresected portion was the tissue surrounding the hilum of the gland. Measured at operation with calipers it was 7 by 4 by 3.5 millimeters, which is slightly larger than the average normal parathyroid. It was estimated that this residual tissue weighed but forty milligrams. If we take the ratio of the tissue left behind to that excised it is 1 to 170 (table 1). This is of no order

TABLE 1

W P. & Aged 39 No. 340457

Parathyroid Hyperplasia

Weight of parathyroid tissue excised

Lft. upper	4.96 grams
Rt. upper	1.83 grams

The second patient was an older person a woman of fifty-seven years. Her major complaints were also built around the renal complications but she had

also lost considerable weight, suffered from marked generalized weakness and had had diffuse bone pain. Four years before she came to us she had had one kidney removed. She was referred to our hospital because of colic in her remaining kidney. A routine x-ray plate taken of her kidney showed bone changes in the pelvis characteristic of hyperparathyroidism. Her blood studies showed the typical elevation of blood calcium and lowered blood phosphorus. Her blood phosphatase was, however, normal. Upon exploring her neck, a large left upper parathyroid tumor was uncovered. Again grossly, a diagnosis of hyperplasia was made. This was immediately checked with a frozen section by Dr. Castleman. Once more it became necessary to isolate all possible parathyroid tissue. Four tumors were identified without difficulty, two large upper and two smaller lower ones, and all except a portion of the left lower were excised.

As with the other patient the problem after exposure of all the tissue was the question of how much to leave behind. Let me summarize the points which were weighed in making this decision. First, the total amount of tumor tissue present was larger than in the case of the man. Secondly, the woman was sicker than the man and would in all probability withstand less well the shift to tetany. Thirdly, although the phosphatase was normal, obvious bone disease was present, which would increase the likelihood of tetany. Fourthly, kidney damage may make it difficult to treat tetany since acidosis occurs more readily. These four points are all in favor of leaving more rather than less parathyroid tissue. On the other hand, one kidney gone and the remaining one partially damaged demanded as rapid a cure of the disease as possible in order to prevent further renal impairment. The existing kidney damage was therefore also a definite indication for reasonably radical resection.

Approximately 200 to 250 milligrams of tissue was left behind. The weight of that which was excised was 11.2 grams. The ratio of remaining to excised was 1 to 49 (table 3). Her operation was on Feb-

ruary 10, 1935, following which she has shown marked improvement, gaining weight and strength with gradual disappearance of her skeletal pains. Her calcium and blood phosphorus have to date remained within normal limits (table 4).

Both of these patients represent an almost lucky removal of sufficient parathyroid tissue, or perhaps an even more lucky removal of not too much tissue. It is impossible to state what would have happened if twice the amount had been left. The disease might have been equally well cured. Likewise if but half as much had

been left it cannot be definitely stated that last- ing tetany would have occurred though it is probable. We have not as yet had sufficient experience. No subtotal parathyroidectomies have been reported from any other clinic. We are by no means on such a sure footing as in surgery of the thyroid.

These two patients had very mild tetany post-operatively which is a thing we like to see. This

tetany very promptly disappeared but it gave us an indication that we had brought about a shift in parathyroid function. Mild tetany of this sort which disappears at the end of a week may be due to a shift, later compensated for, in the blood calcium partition. It may be due to a temporary subnormal parathyroid activity which is quickly corrected either by reactivation or regeneration of the normal or hyperplastic parathyroid tissue left behind.

The difficulty of the operative procedure lies in the evaluation of how much tissue to leave behind. No set rule can be stated as to how many milligrams should be left. In the fatal case with the severest tetany in which subtotal removal of an adenoma was done, far more tissue was left behind than in either of the two cases I have just reported or in two of the other subtotal removals. All of the features of each case must be evaluated and it is essential for the surgeon to understand not only the anatomy and surgical technique of the operation but also the metabolic physiology of the parathyroid glands.

Let me repeat that hyperparathyroidism is a more common disease than usually suspected, that its treatment is surgery, that to accomplish surgical results the problem is not only one of exposing parathyroid tissue but equally one of knowing how much to remove. Subtotal resection may be indicated in the adenoma as well as the hyperplasia group. Overzealous removal of too much tissue may end in graver disabilities than the disease itself.

CHAIRMAN FRENCH: The last paper will be read by Dr. Frank Lahey. His paper is entitled "The Reduction of the Mortality in Hyperthyroidism."

THE REDUCTION OF THE MORTALITY IN HYPERTHYROIDISM*

BY FRANK H. LAHEY, M.D.†

IN discussing the mortality rate of hyperthyroidism, one must appreciate that it can be influenced by a variety of factors not the least of which is the stage in the disease at which the physician sends the patient to the surgeon.

Nearly all physicians today are in agreement with our attitude, that when one can make the clinical diagnosis of hyperthyroidism with certainty, the indication is for surgery. There are, however, some physicians, and I saw this with out implied criticism and with complete respect for their opinion, who prefer to treat patients with this disease expectantly by rest or by radium or x-ray therapy. To these men I would urge if, in spite of these measures there is an increase in the pulse rate, an increasing weight loss and increasing myasthenia or any

on patients who had been operated on for hyperthyroidism five years or over and everyone of whom were seen, examined and a basal metabolism done and have established the fact that 94.8 per cent of these cases were entirely free from all symptoms of hyperthyroidism.

If, as the result of my own personal experience in seeing a large number of patients with hyperthyroidism, I were asked to state what is the most important single feature related to the mortality of the surgery of hyperthyroidism, I believe I would say that it is the preoperative decision as to how severe the thyroid intoxication is and as to whether the patient will probably require multiple stage procedures. I have often stated and, as the result of this extensive experience, more than ever believe it

MULTIPLE STAGE OPERATIONS

	Total Cases	One	Two	Three	Four	Five	Six	Total Operations	Deaths	Case Mortality	Operative Mortality
<i>Toxic</i>											
Primary											
Hyperthyroidism	4521	3220	1517	15	3*	5	2	6427	41	.60	63
Recurrent											
Hyperthyroidism	407	369	41					448	3	.74	67
Adenomatous Goutre with Secondary Hyperthyroidism	1417	1185	216	1*	2	3		1671	28	1.6	107
	6345	4774	1774	164	34	7	2	8546	72	1.1	.84

other signs of an increasing intensity of the disease, that they be promptly turned over to the surgeon for subtotal thyroidectomy. I urge them further, even if they remain stationary but do not show prompt and definite improvement under these measures that they be turned over to the surgeon for subtotal thyroidectomy. If the physician in charge of a patient with hyperthyroidism permits her to get into a severe state of intoxication before sending her to a surgeon he is directly responsible for the increase in the chances of a fatality which, if the disease is advanced, in all probability she must eventually face. The longer patients have hyperthyroidism, the greater the operative risk. It must be admitted as I will show in the slides, that subtotal thyroidectomy today in the hands of an organized thyroid clinic can and does cure patients of hyperthyroidism within a few weeks of its application and with an extremely low mortality rate.

We have published elsewhere follow up figures

to be true that the time to make one's decision concerning the probable risk of operative procedures on patients with hyperthyroidism is when they are first seen. This is the time when patients with this disease are at their worst, most apprehensive, often having journeyed some distance to consult us, frequently uninfluenced by the employment of iodine and emotionally upset from facing the ordeal of a possible surgical procedure. If the decision as to the degree of thyroid intoxication is made at this time and recorded on the patient's record as to the probability of multiple stage operations and their number, it will be done under conditions which will be on the side of safety. If, on the other hand a decision as to multiple stage operations be deferred until such a patient has been resting a day or two in the hospital, if she is seen in bed at rest under iodination, after being quieted by hypnotics after forcing fluids and after having adjusted herself to her new surroundings, one may readily be misled into believing that such a patient will withstand a one stage complete subtotal thyroidectomy with safety. Likewise, under these conditions, it is easily possible to forget

Read at the Annual Meeting of the Massachusetts Medical Society Section of Surgery, Jun. 4, 1933.

*Lahey, Frank H.—Director of Surgery, The Lahey Clinic. For record and address of author see "This Week's Issue," PAGE 499.

how impressively toxic the same patient appeared two or three days previously when first seen at the office or in the clinic at the time of the first examination. We believe, therefore, that one of the outstanding requirements to diminish the mortality in the surgery of hyperthyroidism, is that a decision as to the degree of toxicity and the necessity of multiple stage operations be made when the patient is first seen at his or her worst.

The preparation of patients for the surgery of hyperthyroidism plays a considerable part in lowering the surgical mortality of this disease and it is important to have quite clearly in mind what one aims to do and desires to accomplish by this preparation. I have often stated that it is much better to think of hyperthyroidism rather in terms of hypercombustion than in terms of intoxication, since if one does this, one can appreciate that the purposes of all methods of preparation are one, to diminish the activity of the thyroid, the hypersecretion of which stimulates excessive combustion, and two, during this time to combat the destructive effect of excessive combustion by providing a substitute for the excessively stimulated organism to burn in order that it may not consume itself.

While I cannot undeniably establish the fact that the deaths associated with excessive hyperthyroidism are largely liver deaths, I have personally for a number of years been convinced of this fact and with widening experience, am more and more sure of it. As I have watched patients who have come to us in advanced stages of thyroid intoxication and who have died unoperated in extreme thyroid crises and as I have critically observed severe postoperative thyroid reactions, the probability of the previous explanation of a thyroid fatality seems more and more convincing to me, some of the evidence concerning which I submit.

It is not at all uncommon for unoperated patients who die in extreme states of hyperthyroidism to show jaundice in the terminal stage of their intoxication and in the entire absence of any evidence of gall-bladder or liver infection. This jaundice is of the hepatogenous and not the hematogenous type. Patients with severe and fatal hyperthyroidism as in those with liver damage, usually die with high and unexplained temperatures (105-106°) unassociated with operative procedures and unassociated with any evidences of infection. Patients with excessively and dangerously severe hyperthyroidism are strikingly benefited by the measures which prove so useful in patients with liver damage such as glucose, fluids and blood transfusion and finally, it has been definitely demonstrated that in the presence of a severe hyperthyroidism, there is a diminution in the glycogen reserve in the liver, a factor

which is so constantly valuable in protecting that organ against damage.

One may lessen the undesirable effects of excessive metabolic activity by rest in bed, thus lightening the metabolic load upon the organism, created by the demands of up and about activity. For this reason, we place all patients with hyperthyroidism in bed at rest for an average period of eight days before operation. During this time Lugol's solution, ten minims three times a day, is given, because Dr R. B. Cattell working in this Clinic in nineteen twenty-four on the effect of iodine upon the histology of the thyroid, demonstrated that in ninety per cent of the cases involution of the hyperplasia associated with hyperthyroidism would occur in these cases treated with Lugol's within this period of time. During this period of bedrest, patients are allowed to be up and about one hour in the morning and one hour in the afternoon in order that they may retain some of their muscular and vascular balance. They are placed upon a high carbohydrate diet in order to increase their glycogen reserve as much as possible and the endeavor is made to maintain a food intake which will not only keep them from losing weight but if possible, cause them to gain weight during this time. It is obvious that the arbitrary selection of eight days must often be extended to meet the needs of individual cases. In the average case, however, eight days will suffice to prepare these patients for operative procedures safely. In the very serious cases it frequently becomes desirable to augment such measures by the additional employment of constant intravenous fluids, concentrated glucose solution and intravenous iodine for two or three days previous to the operative date.

Nothing, in my opinion, is more important in reducing the mortality in the surgery of hyperthyroidism than the anesthesia, and the anesthesiologist. Ether is a distinctly undesirable anesthetic for patients with hyperthyroidism and I believe that the two chief reasons why ether is so undesirable at this time are as follows. One, the degree of excitation associated with its induction and two, the amount of postoperative vomiting which is associated with it. One must always be conscious of the fact that vomiting is a bad and at times fatal complication of hyperthyroidism, pre- or postoperatively or in a patient who is never to be operated upon. Vomiting unbalances metabolism since the overstimulated combustion associated with hyperthyroidism goes progressively on while the ability to take in fluids and fuel, and thus at least in some measure to offset the ravaging effects of hypercombustion, is lost. For these reasons, ether should never be used in patients with hyperthyroidism.

There have been many and ardent advocates of local anesthesia in patients with hyperthy-

roidism, an attitude with which I have never been in accord. Patients with hyperthyroidism are apprehensive and are emotionally sensitive. Their pulse rates during operation as the result of this apprehension and emotional ordeal are abnormally stimulated, thus distorting practically the sole guide we have during the operative procedure as to the degree of dangerous reaction. As with spinal anesthesia, because patients are awake and conscious, we are often wrongly misled into a false impression that such patients are safer by being protected from the undesirable effects of a general anesthetic. Just as with spinal anesthesia, this is in a measure true, but they are likewise often suffering doubly undesirable other effects. Local anesthesia in our opinion gained its greatest popularity as a substitute for ether and of the two, there is no doubt as to the superiority of local anesthesia but since we have had other general anesthetics which do not have the disadvantage of ether, local anesthesia producing as it does an emotional ordeal for the patient and in some measure likewise for the surgeon, has little or no place in subtotal thyroidectomy for hyperthyroidism.

Nitrous oxide is superior as an anesthetic to either of the two previously mentioned anesthetics, and up to the time that we had better gas anesthetics, it was the best of all the methods of anesthetizing these patients. Its greatest disadvantage is that a nitrous oxide mixture sufficient to maintain a satisfactory anesthetic depth contains only approximately nine per cent oxygen. If there is one thing that patients with excessive thyroid secretion and so excessive metabolic activity demand, it is sufficient oxygen. Nitrous oxide anesthesia with its considerable degree of anoxemia is far from a desirable anesthetic for patients with this disease and when compared with the other anesthetic to be mentioned later, with higher oxygen mixtures it will in severe cases not infrequently enhance the scale on the side of a fatality.

Ethylene has been one of the greatest anesthetic advances in surgery and particularly as relates to anesthesia in the surgery of hyperthyroidism. It is a powerful anesthetic making control of these activated patients relatively easy. It has an oxygen mixture of approximately fifteen per cent and patients can be maintained under it without anoxemia. We have given it in several thousand cases without a semblance or suggestion of an explosion and if proper precautions are taken this danger is no greater than with other anesthetics as they are usually given.

We come now to one of the greatest advances, I believe, in the gas anesthetics and particularly in relation to the anesthesia for patients with severe hyperthyroidism, that is, cyclopropane. Cyclopropane is a hydrocarbon gas anesthetic C_3H_6 which is very similar to ethy-

lene. It is slightly more explosive than ethylene, it is much more powerful than ethylene but it has the great advantage of maintaining an oxygen mixture of approximately eighty-five per cent. When one realizes how necessary oxygen is to these patients with markedly increased metabolic processes, it is evident that when one can employ an anesthetic with this high percentage of oxygen it is an extremely desirable one. We have now employed cyclopropane since October, nineteen thirty-three, in something over a thousand cases. We are using it more and more frequently for patients with intense hyperthyroidism who are extremely ill and it will, I prophesy in spite of its added cost as compared with ethylene and nitrous oxide, prove to be the anesthetic of choice for the surgery of patients with hyperthyroidism.

There is no place in surgery where expert and thyroid experienced anesthetists play a part in reducing mortality more than in the surgery of hyperthyroidism. Once the anesthetic is started, the surgeon is dependent on the anesthetist's decision as to how well the patient is standing the operation and whether it should be limited to a hemithyroidectomy or a subtotal thyroidectomy. There is no place in surgery where clinical judgment and experience on the part of the anesthetist are needed more than in the management of the anesthesia and patient during a subtotal thyroidectomy on a patient with severe hyperthyroidism.

Several times in our experience, patients' lives have been saved by our experienced anesthetists, by the immediate introduction with the laryngoscope of an intratracheal catheter through the vocal cords necessitated by spasm of the larynx or tracheal obstruction. Furthermore, anyone who has done many serious thyroid operations must be extremely conscious as I often have been, of the fact that the decision as to whether a tracheotomy must be done, must be almost entirely in the hands of the anesthetist. It is he who must finally say "This patient is not getting enough air. She must have a tracheotomy." If it is true, as everyone must admit, that to maintain a low mortality rate in thyroid surgery demands organized effort, then an all important element in that organized effort is undoubtedly an anesthetist experienced with thyroid conditions.

Some of the features immediately observable during the operation which are an indication of danger, a possible mortality and should lead the surgeon to limit the operative procedure are recorded here. If surgery be persisted with and complete subtotal thyroidectomies done in the face of progressively rising pulse rates while on the operating table there will be a distressingly high mortality rate. If surgery be persisted with in the presence of a persistently widening pulse pressure, there will be a high

mortality rate An indication of danger during the operation also is an increasing demand for oxygen on the part of the patient and an increasing difficulty in maintaining depth of anesthesia.

There are certain generalizations as to preoperative indications for multiple stage operations such as the youthful stand hyperthyroidism and the surgery for it better than do the middle-aged and old

Patients who show marked improvement and weight gain under iodine are better operative risks and better prospects of successfully withstanding one-stage operations than are patients who do not show improvement and who show weight loss

Patients who have been vomiting or who as the result of the disease have had recent diarrhea are notably bad risks

Children with hyperthyroidism are uncertain risks, largely because of one's inability to settle what is really reaction to thyroid intoxication and what is the children's capacity to react unduly to any intoxication In children, therefore, I have always maintained that because of this uncertainty it is safest particularly in the severe cases, to do two-stage operations

Weight loss in spite of a good appetite is an indication of the effect of a severe hyperthyroidism

Everyone who has dealt with hyperthyroidism appreciates that while it can exist for a long time and after subtotal thyroidectomy patients are apparently as well as they were before they had it, nevertheless, patients who have had hyperthyroidism for a long time stand operative procedures less well than do those who have had it for a short time

Age and its associated infirmities and damaged organs undoubtedly play a considerable part in the mortality of patients submitted to subtotal thyroidectomy for hyperthyroidism The mortality in patients past middle age is distinctly higher than in the lower age group, a fact which compels two-stage procedures in this group in spite of any apparent seriousness of risk

As may be seen by the operative figures, one does well to remember in foreseeing possible multiple stage operations that the mortality of patients with toxic adenomata has always been at least twice that of patients with apparently more severe and undoubtedly less dangerous primary hyperthyroidism or exophthalmic goitre

One should recall always the group of cases which I described under the term apathetic hyperthyroidism and appreciate that this is the group of cases in which no warning as to a possible fatality is given by the usual danger signs, excitation, activation, increased pulse rate and

impressive elevations of metabolism This is the type of case in which it must be realized that the patient is suffering from apathetic hyperthyroidism, and two-stage operations in such cases must be done not because of any striking danger signals but as a precautionary measure since we have learned and preached now for some time that it is in this type of case, not apparently very toxic, that stands the immediate operative procedure quite well that the latent unanticipated postoperative fatality occurs It is in the apathetic type of hyperthyroidism that we unhesitatingly do two-stage procedures, regardless of how well they appear or how well they are enduring the operation

There are certain technical necessities which have to do with mortality rates in subtotal thyroidectomy for hyperthyroidism While thyroid operations do not need to be rushed, we know from our experience with them that patients with hyperthyroidism do not satisfactorily withstand prolonged operative procedures One, therefore, needs to be expeditious in the surgery of hyperthyroidism Likewise, patients with hyperthyroidism do not stand blood loss well It is, therefore, important that bleeding be accurately controlled While on the subject of bleeding, it is extremely important to state that the avoidance of postoperative hemorrhages is directly related to the care with which vessels in the thyroid are caught and ligated and likewise distinctly influences mortality rates It is not usually appreciated how serious it is to have a postoperative hemorrhage in a patient with severe hyperthyroidism This complication is not only undesirable from the point of view of blood loss, but it is doubly undesirable from the fact that it tends to occur at a time when the patient is in a state of postoperative reaction, thus intensifying his already severe hyperthyroidism, that this must be further intensified by either an anesthesia in bed or a visit to the operating room and another anesthesia If there are many postoperative hemorrhages in patients with severe hyperthyroidism, there will be an unduly high mortality rate associated with these cases It is for this reason that we have never been interested in controlling hemorrhages in thyroid glands by suture, preferring to avoid postoperative hemorrhage by accurate ligation of each vessel With these precautions in our experience, we practically do not have to deal with the matter of postoperative thyroid bleeding

No patient who has been submitted to subtotal thyroidectomy should ever leave the operating table with any doubt as to whether that patient is breathing well If there be respiratory obstruction, the operating team should remain sterile, the patient be kept draped upon the table and unless within a reasonable time with the anesthetic off and no oxygen provided

the patient breathes freely and clearly, the anesthesia should be resumed, the wound reopened, the trachea exposed, the cause of obstruction demonstrated and removed and the patient sent back to bed breathing freely. If this cannot be done and interference with respiration persists, then a temporary tracheotomy should be done. As has already been stated, there is no better way to bring about a fatality in patients submitted to subtotal thyroidectomy for hyperthyroidism than to permit them to return to bed suboxygenated, cyanotic and anoxicemic. When such patients finally convince the surgeon that they are not breathing satisfactorily and are then submitted to a tracheotomy they frequently never regain consciousness and in spite of all measures, ultimately die. If there is a dependable maxim as relates to respiratory obstruction following surgery for thyroid disease, it is that patients must leave the table breathing well and if there is doubt due to partial tracheal obstruction as to whether a tracheotomy is necessary, then the tracheotomy is necessary. It is infinitely better to do a temporary tracheotomy which is properly placed and will close uneventfully than to wait until one is convinced of its need but find it then too late.

In discussing the proper location for tracheotomy, we have learned from Dr. W. B. Hoover of the Laryngological Department in the Clinic that the best place for a tracheotomy is not the place where it is most easy to do it. The tendency for inexperienced tracheotomists is to make the tracheotomy high where the trachea is readily reached. As Dr. Hoover has demonstrated to us, this is the point where the trachea is narrowest, this is the point where stricture is most apt to occur. When we do them, we place them low in the trachea as he has taught us to do where the tube may remain temporarily without discomfort and where the trachea will close readily without constriction after the removal of the tube.

The postoperative care of patients submitted to surgery for severe hyperthyroidism undoubtedly plays a very large part in the control of mortality. If patients are vomiting postoperatively, they need fluid, not in the form of fluid at intervals but they need fluids and fuel constantly. This is best given by tying an intravenous Henderson needle in the long saphenous vein just above the ankle and by running into the vein five per cent glucose in salt solution at the rate of thirty to sixty drops per minute during the entire twenty-four hours. Into this

may be introduced fifty minims of Lugol's solution which we demonstrated several years ago could be given intravenously with impunity, supplying thus even in patients who are vomiting the much needed postoperative iodine. During postoperative reactions, no matter what anesthetic is employed, particularly in patients with severe hyperthyroidism, there is a tendency to vomit, cutting off thus the natural source of intake of fluids and fuel. One must realize that during this stage the height of the excessive combustion is either constant or upward and that if fluids and fuel are introduced only at intervals there will be periods when the individual will be burning himself. If on the other hand fluid and fuel are introduced constantly by the intravenous drip, then the patient is at least in some measure being protected against the excessive combustion process until the effect of the subtotal thyroidectomy becomes active, lessens the output of thyroxin and lowers the metabolism.

CONCLUSIONS

These warnings and measures aimed toward helping others maintain low mortality rates in the surgery of hyperthyroidism, are the result of a number of years' experience and contact with a large number of patients suffering from this dangerous disease. They represent practical deductions based upon distressing and worrisome actual experience with patients in these serious states. They represent my own and the combined efforts of an organized group to accomplish, maintain and progressively lower mortality rates in the surgery of this serious, uncertain and fickle disease. From our earliest experience with it, I have been of the opinion have frequently stated and have become more and more convinced that the surgery particularly of hyperthyroidism differs considerably from that of other lesions and that it must be dealt with differently, and that to keep the mortality rate low it requires an organized effort on the part of several different individuals representing different branches of medicine. When it is dealt with casually by individuals as with appendicitis, hernia, fibroids, and so forth, the mortality will be distressingly high but when it is dealt with by an organized group dealing with these cases in numbers the mortality rate will be surprisingly low, the complications agreeably rare and the end results as gratifying as those following any operation in surgery.

[Meeting adjourned]

MEDICAL PROGRESS

THE PROGRESS OF NUTRITION

BY FRANCIS LOWELL BURNETT, M D *

DEFICIENCY DISEASES, ARTHRITIS AND HEALTH

"IT is difficult to implant the idea of disease as due to deficiency. Disease is so generally associated with positive agents, the parasite, the toxin, the *materies morbi*—that the thought of the pathologist turns naturally to such positive associations and seems to believe with difficulty in causation prefixed by a minus sign.

Even when Eijkmann had clearly established that beri-beri arose during the consumption of decorticated rice he was led to suggest not the simple view that the cortical substance was of direct use to the body but rather that it was necessary to neutralize the otherwise deleterious effect of a diet over rich in starch.

The mental bias in every case has certainly been to delay the recognition of deficiency diseases" (Report on the Present State of Knowledge concerning Accessory Food Factors. His Majesty's Stationery Office, London, 1919, pp 2-3).

Since this opinion was expressed, many deficiency diseases have become recognized, and among them are two, rickets and osteomalacia, which are essentially diseases of the bones. Is it possible that a continued mental bias prevents the recognition of arthritis, another chronic disease of the bones, as a deficiency disease and one due to malnutrition? Some time ago Nichols, E H, and Richardson, F L (*J Med Research* 16 149, 1909) in their classical study of the disease suggested this point of view by the assertion that it was due to "faulty metabolism." Recently, such an assertion has been confirmed experimentally by Rinehart, J F, Connor, C L, and Mettler, S R (*J Exper Med* 59 97, 1934) through the production of arthritic lesions in guinea pigs from a scorbutic diet. And from the clinical standpoint, Minot, G R (*New Eng J Med* 208 1285 [June 22] 1933) has written "little is known concerning the difficulties of absorption and utilization of food products from the digestive tract and regarding what particular food factors may improve gastrointestinal function."

It is probable that significant degrees of such disturbances may arise in arthritis and be overcome by well-chosen diets."

The most fundamental disorder perhaps, in the development of deficiency diseases, is the failure of normal nutrient substances to unite with the protoplasm of cells, to maintain them in a healthy state. Such a disorder is often man-

ifested by diametrically opposite structural changes in the tissues. In the most common, as shown in most deficiently fed animals and observed in the skin of patients with pellagra by Denton, James (*Am J Path* 4 341, 1928) is a general atrophy of the cells. But in the other, as shown in vitamin A deficiency in many animals and observed in the bone marrow of patients with pernicious anemia by Peabody, F W (*Am J Path* 3 179, 1927) is a hyperplasia of abnormal cells. Although these structural changes are undoubtedly an indication of faulty metabolism, their exact significance at present is beyond comprehension. Oddly enough, some what similar kinds of structural changes occur in the atrophic and hypertrophic types of arthritis, and thus the deficiency origin of this disease is pertinently suggested. As a consequence, if the cause of deficiency diseases is eliminated by the ingestion of complete food, the cause of arthritis may be also removed by "the selection of well-chosen diets" to improve nutrition.

Such a point of view has been taken by Burnett, F L, and Ober, F R (*Am J Med Sc* 188 93, 1934) and described in principles of treatment for this disease. On this theory, the construction and maintenance of cells in anabolic or normal nutrition, must be regarded as a complex and delicately adjusted process, which is brought about by the complete digestion and absorption of food, from the operations of a perfect nutritive apparatus. Under these circumstances, erroneous ways of eating and living must be corrected and controlled to produce the normal indices of absorption: the entirely segmented feces and normal intestinal rates, and thus create a previously unrecognized and improved state of health to cure disease. Thus, the well-chosen diet is made subservient to a normal function of the colon, and in amount, completeness, proportion, and preparation for digestion, must be about right for the construction of cells, or else it is rapidly propelled onward by an abnormal function of the colon that resembles vomiting by the stomach. In this way abnormal feces and rapid intestinal rates are an indication of malabsorption, by which nourishment goes through instead of into the body, and the cells of the bone do not receive the normal nutrient substances they require to be healthy. In the practice of these principles, it was not surprising to find from an analysis of the answers given by thirty arthritic patients, that all had one or more erroneous ways of eat-

*Burnett Francis L.—Director of Health Class for Psoriasis Massachusetts General Hospital. For record and address of author see This Week's Issue page 499.

ing or living to correct to become better nourished and healthier. For nineteen were found who ate too fast and too much, seventeen took laxatives, oil, or enemata regularly, nineteen were physicked by too much fruit, especially oranges and grapefruit, ten were accustomed to eat candy, cakes, crackers, or fruit between meals, eight consumed an excess of bread, cake, macaroni, and other acid cereal food, six ingested too much meat and fish, and five were too fond of fat food. In the treatment of the disease however, an attempt was made to educate 241 patients, but as months and sometimes years are often required to become better nourished and healthier, intelligence, coöperation and perseverance are necessary, if these chronic invalids are to learn the normal action of the nutritive apparatus from the correction of erroneous ways of eating to become relieved of disease. These perquisites were not generally obtained, therefore subtracting eighty nine who could not understand the principles, and thirty four who would not coöperate and carry out the requirements, leaves 118 patients, on whom the results of treatment are based. Of this number forty three became healthy, and some of them have continued so by reporting to the health class or office with a record, once in a while, then, seventy five became greatly improved, and some of them would have become healthy if they had carried on treatment long enough, and finally, seven tried once failed and became worse, then took up treatment again, and have improved.

Unlike others, in these principles of treatment as an exact state of health are evidently taken into account to cure disease, it is obvious that former patients must subsequently control anabolic or normal nutrition, if this improved state of well being is to be maintained. Consequently patients must not only be taught how and what to eat to create anabolic nutrition and relieve the disease, but they must also be supervised afterward to be sure that they carry out the requirements of this complex and delicately adjusted process, to prevent a recurrence by the control of health.

FOOD, HEALTH, AND NUTRITIVE DISORDERS

A report by the Minister of Health (His Majesty's Stationery Office, London, 1934) on the food requirements of the English people, recommended 3,000 calories for the average man a day but a man doing heavy work might need 4,000, and an inactive one might get along on 2,600. Women required less food, but growing boys and girls from ten to eighteen years old needed 2,300 to 3,400 calories. The protein requirement was set at 80-100 Gm., of which one third must be of animal origin, and the need of foods containing the vitamins was emphasized. An International Conference on vitamin

standardization met in London last year (*J. A. M. A.* 103:353 [Aug. 4] 1934), and the following recommendations were adopted: For vitamin A optically inactive beta-carotene, which has a melting point of 184 degrees Centigrade has replaced impure carotene, for vitamin B, the adsorbate on acid clay has not been changed, for vitamin C, L ascorbic acid as defined by physical constants has been substituted for lemon juice, and for vitamin D, the old standard of cholesterol in olive oil had been continued.

In many of the English colonies, health officers have studied and reported on the health of the people (*Nutrit. Abs. & Rev.* 4:150, 1934). In Nigeria, the staple food of guinea corn has been supplemented by cassava and sweet potatoes, and thus the diet has been made more complete and better proportioned. In Bechnana land, 33 per cent of the natives examined were rejected for work in the gold mines on account of poor physique. Inquiries of the food consumed by eighty of the children, revealed that sixty had had no food for eighteen hours previous to the examination and ten had had no milk for three months. Maize porridge was the staple diet, except in the summer months when they got a little milk, wild spinach, and pumpkin. In Swaziland, tuberculosis was prevalent, and was ascribed due to a diet low in protein and deficient in vitamins, because when patients with incipient tuberculosis of the glands or the joints were admitted to the hospital and were given complete and well proportioned meals, they rapidly recovered.

A comparison of the stature of young English children of the professional and artisan classes, has been made by Spence, J. C. (*Nutrit. Abs. & Rev.* 4:375, 1934), and in examinations those of the former were found taller and heavier. In those of the latter, only 33 per cent were in good, 20 per cent were in poor, and the remainder were in mediocre condition. And in tests of blood from these children 20 per cent had a hemoglobin of more than 75 per cent, 23 per cent had less than 65 per cent and the remainder had blood values between these percentages. The cause of such deficiencies in the artisan children was thought due to inadequate diets and previous infectious diseases. In a study of the eating habits of rural school children in relation to their condition by Brown (*Utah Agr. Exper. Stat. Bull.* No. 246, 1934), 82 per cent were found to drink milk regularly, 73 per cent to eat raw vegetables daily, and 58 per cent were accustomed to eat raw fruit and 48 per cent to eat bread and jam, between meals. Dental caries, gingivitis and abscessed teeth were prevalent, and defective vision, diseased tonsils, enlarged thyroids, and poor skeletal development were some of the other defects found in the children. Many too were found underweight, and these had had a poor diet compared with those up to or above the Bald

win-Wood standards From clinical and experimental evidence presented by Schiff (*Arch Pediat* 51:769, 1934) diarrhea in infants was not thought due to the fermentation of carbohydrates, but an excess of fat foods obviously irritated the colon For the disorder a mixture composed of 300 cc of Ringer's solution, 600 Gm of 10 per cent rice jelly, and 50 to 60 Gm of pure glucose was advocated, and the amount given was made proportionate to the child's weight After improvement began a buttermilk mixture was cautiously added to the food

An analysis of the dinners served in a student's mess, in a public kitchen, and in an army kitchen, of Germany has been made by Remy, Edward (*Arch f Hyg u Bacteriol* 113 143, 1934) The average amount of food served at these meals was 1338, 1056, and 1569 calories, in the order given, and the amount of protein was 37.4, 27.3, and 48.5 Gm, and that of fat was 84.3, 35.1, and 36.9 Gm The Ca, Fe, and Cu were found adequate in all of the meals, but the K was found sufficient only in those of the public kitchen, and the P was adequate only in the army rations Voigt, J M (*Pflüger's Arch Physiol* 234 570, 1934) has studied the utilization of food in man, and found that meat added to the vegetarian diet reduced the loss of nitrogen in the feces And also, that the retardation in the passage of food through the intestines increased its utilization The effect of acid ash and alkaline ash foods on the acid-base balance of man has been reported by Bischoff, F, et al (*J Nutrition* 7 51, 1934) Sodium citrate was used to make the food basic, and 30 Gm of this salt had to be ingested daily for some time before a change occurred in the reaction of the blood drawn before breakfast The ingestion of 240, 204, and 93 Gm of protein on three consecutive days, and 200 cc N acid equivalent of ash daily, were required before a slight shift was perceptible in the alkalinity of the blood The consumption of a quart of milk, or of orange juice, or a pound of bananas, did not change the plasma pH or the reserve of alkali, but the ingestion of a pound of steak had a slight effect on the plasma bicarbonate in one out of four persons tested

The food consumed by native South Africans has been studied by Cluver, E H (*South African M J* 8 19, 1934) and found deficient in vitamins and excessive in carbohydrates Mealie meal was the principal article eaten, and frequently laborers arrived at the mines in a pre-scurbutic condition The companies however added meat and vegetables to the food of their laborers, so that after working a year the men became much healthier The race of Bantus were commonly found suffering from pellagra, and many of the natives from Zululand and Transkei were in a sub-pellagrous condition In Manchuria, the food of the Chinese has been

found complete and well proportioned by Lu, T H (*J Orient Med* 20 22, 1934) Little sugar and fruits were eaten by the middle and lower classes, but the amount and variety of cereals, vegetables, and germinated seeds consumed furnished an adequate supply of vitamins B and C especially In China deficiency diseases were found prevalent and to prevent them Wu and Wan (*Nat M J China* 20 29, 1934) have composed and tried vegetarian diets on some Chinese subjects One diet composed of thirty-five parts of roasted peanuts, thirty-six of whole wheat, ten of millet, ten of roasted soya beans, five of wheat bran, and four of a salt mixture, and green vegetables ad libitum, produced good growth, but was insufficient for reproduction and lactation The addition of animal food made this diet adequate Another diet composed of twenty-five parts of soya beans, fifty of millet, ten of corn, four of roasted soya beans, ten of whole wheat, and one of salt mixture, which was similar to the food by the people of Northern China, was not even adequate for the growth of children, unless two eggs or 34 Gm of beef or pork were added each day Le Méhaute, P J, and Tcherniakofsky (*Bull Soc scient d'hyg aliment* 22 4, 1934) have published an interesting report on the food of the Eskimos These people eat all parts of the seal, whale, musk ox, and polar hare with the exception of the gall-bladder, also some Arctic birds, their eggs, salmon, and cod, varied with the other animal food And the contents of animals' stomachs, algae, bill berries, juniper, dwarf willow, sorrel, and dandelions, furnished most of the vegetable food The amount of food consumed could not be estimated, as they always ate irregularly Scurvy was not evident but a few patients with rickets were seen

In a review of the pathogenesis of deficiency diseases, Strauss (*J A M A* 103 1, [July 7] 1934) has pointed out that they frequently develop in spite of an adequate diet, and apparently on account of a disorder of the gastrointestinal tract A similar observation has been made by Goudsmit, J (*Nederl tijdschr v geneesk* 78 3123, 1934) by which patients may develop pellagra or beri-beri after long periods of gastrointestinal disorders Under these circumstances, the deficiency diseases may not be caused so much from a deficient diet, but from a failure to absorb the vitamins The features of Gee's disease have been described by Bennett (*Lancet* 227 739, [Oct 6] 1934) Diarrhea was the outstanding disorder, but also anemias of different types, acute or latent tetany, and infantilism with changes in the bones that resembled osteomalacia, were found Such disorders were considered due to malabsorption rather than to fat indigestion, and therefore in treatment patients were put on a low fat diet, given large doses of iron and daily doses of calcium lactate, and vitamin B and liver as indicated Ohly, A (*Arch f Verdauungskr*

55 254, 1934) has described the sequelae that occur in patients after bacillary dysentery. As a result of the disorder the gastrointestinal tract is in a very unstable state and slight indiscretions often cause relapses. On this account after an attack patients were advised to eat protein extracts of animals only or raw milk diluted with lime water, later finely divided carbohydrates were allowed, and finally after weeks of treatment, foods containing cellulose were given. Interesting observations have been made by Handelsman, M. B., Golden, L. A., and Pratt, J. H. (*J Nutrition* 83 479, 1934) on the effects of various diets on the absorption of depancreatized dogs. The absorption of the animals immediately after the operation was not very abnormal, but later an enormous amount of food was required to maintain body weight.

VITAMIN A, EYE DISORDERS, AND INFECTION

An elaborate review of the clinical effects of vitamin A deficiency in children has been made by Mackay (*Arch Dis Child* 9 65, 1934). In it the geographical distribution, the season and age incidence, the dietary cause, and the period of development of xerophthalmia and keratomalacia, were described. A study was also made by this investigator (*Ibid* 9 133, 1934) of the effect of a large amount of vitamin A on the health of children. The control group ingesting vitamin A normally, showed no difference in the rate of growth, in general health, or in freedom from respiratory infections, specific fevers or metabolic skin diseases, but experienced double the incidence of minor infective skin diseases. The incidence of vitamin A deficiency in Ceylonese school children, factory workers and patients in an asylum, has been analyzed by Nicholls, L. (*Indian M Gaz* 69 241, 1934) and prurioderma was the most, and sore mouth the next most common symptom, observed. Keratomalacia, neuritis, and diarrhea, often accompanied the other symptoms. The food consumed contained very little of the fat soluble vitamins, and consisted mostly of rice and dried fish, very little meat and only a few vegetables during the season, were eaten, and highly stimulating condiments were universally used. Cutaneous manifestations of vitamin A deficiency in a young boy have been described by Goodwin, G. P. (*Brit M J* 2 113, 1934). The skin was found dry and generally covered with a papular eruption. The patient also had pyorrhea and the sclerae were of a yellow tint, but xerosis or night blindness was not evident. A good general diet, including meat and vegetables which it had lacked before, and substantial doses of cod liver oil, brought about a rapid recovery.

Visual tests with a Birch Hirschfeld photometer, have been used by Jeans and Zentmire (*J A M A* 102 892 [March 24] 1934) to de-

termine moderate degrees of vitamin A deficiency in children. Out of 213 patients examined, forty five were found to have incipient night blindness, but, after a diet rich in vitamin A for a few weeks, signs of this disorder had entirely disappeared. Fransson (*Hospitaltid* 77 42, 1934) has applied hemeralopia as a sign of vitamin A deficiency and has found it in forty six out of sixty five apparently healthy school children. The disorder was also found in twenty-one out of twenty six supposedly healthy adults, and in seventy of seventy two private patients who complained of eye trouble. The Ca and P in all of these patients too, were diminished and by the use of haliver oil for several weeks the hemeralopia disappeared, and Ca and P of the blood became increased. A patient with night blindness has been reported by Wilmer, D. L., and Eusterman, G. B. (*J I M A* 102 364, 1934). The ocular disorder became apparent after the patient had had diarrhea for a year as a result of a gastrocolic fistula. The short circuit of the bowel was an operative measure to relieve a duodenal ulcer. The food consumed had contained liberal amounts of vitamin A, but on account of the malabsorption the vitamin went through instead of into the body.

From the available clinical and laboratory evidence Mackay, H. M. M. (*Lancet* 2 1462, 1934) has noted the relation between dietetic deficiencies and the susceptibility to infection in children, and has arrived at the following conclusions. A deficiency of vitamin D lowered the vital resistance especially to respiratory infections and one of iron produced an anemia, and made the children susceptible to common types of infection. A severe deficiency of vitamin A was often associated with a high morbidity, while a mild one generally resulted in skin infections, and one of vitamin B was frequently followed by infections of the respiratory or gastrointestinal tracts. Observations on the use of vitamin A to prevent colds, have been described by Shibley, G. S., and Spies, T. D. (*J A M A* 103 2021, 1934). In this experiment 200,000 international units of vitamin A and 4,000 units of vitamin D were given weekly to 24 young adults, and examinations made at intervals afterward. The results were somewhat disappointing, for the measures apparently had no effect on the incidence or severity of common colds but may have reduced the time some of the colds lasted during the winter months. A somewhat similar study has been made by Gardner, E. L., and Gardner, F. W. (*Am J Dis Child* 47 1261, 1934) but with more encouraging results. Three groups of children of about the same age of equal sexes, and of about the same general condition were observed. To one, 10,000 units of vitamin A in the form of haliver oil were given daily, to another a diet was given which contained a similar amount of the vita-

min, and to a control group, only a good general diet was prescribed. In contrast with the previous observations, the specially treated groups showed a marked decrease in the incidence and severity of the colds, and also made more of an increase in weight and an improvement in health.

BERI-BERI, PELLAGRA, AND NERVE DISORDERS

In an analysis of the incidence and symptoms of beri-beri from a study of 109 patients Yang, C S, and Huang, K K (*Chinese M J* 48 20, 1934) found the disease in only four women, and seventy of the men were in the third decade. Then of the total number, sixty-one presented neuritic only, nineteen had neuritic and edematous, and twenty-nine cardiac symptoms, and in the edematous patients the serum protein was not diminished. Some of the patients developed the diseases after a febrile attack, and especially malaria, but the majority of those consuming inadequate food developed it as a result of excessive physical exertion. These authors (*Ibid* 48 701, 1934) too have reported an outbreak of pellagra in some young Chinese soldiers. Of the thirty patients diagnosed, all of them had the typical dermatitis, many had glossitis and also night blindness, and some had colitis. The gastric juice, and especially the HCl, was found reduced. The diet consisted of rice, wheat flour, greens, vegetables, and pork, there was an absence of maize and a low protein content. The conclusions arrived at from the study were that the disease was a symptom complex and not due to the deprivation of a single food factor.

Several patients that developed beri-beri as a result of gastrointestinal disorders have been reported. Among them Riesman, D, and Davidson, H S (*J A M A* 102 2000, 1934) have described the case of an old man, who on account of gastric pain and discomfort for some time had eaten very little food. After being fed with a tube for several days, the symptoms disappeared and his appetite returned, so that subsequently he consumed a liberal diet, and the edema of the legs and the disease were relieved. They also described the case of a young woman, who on account of obesity lived for some time on a very restricted diet. She developed edema and shortness of breath but when informed of the cause of her complaint, she consumed more food and was promptly relieved of the symptoms and the disease. Similarly, Urmy, T V, et al (*New Eng J Med* 210 251, 1934) described a patient, who on account of a surgical operation had a short circuit of the gut and developed beri-beri. He was able to eat sufficient and complete food, and thus the disease was the result of a failure of absorption. Treatment with a concentrate of yeast was of some value, but it was not until the digestive

system was made more normal by another operation that the disease was relieved.

Many of the Jews of Constantinople have become pellagious, according to the opinion of Sinai I (*Ann d'ig* 44 245, 1934) who thought the disease due to the excessive consumption of unleavened bread for a long time after the Passover. A disease, which Corkill, N L (*Lancet* 1 1387, 1934) has called pellagra was found prevalent among the Arabian women of Anglo-Egyptian Sudan. The characteristic dermatitis was not observed, but instead the sebaceous glands of the face were hypertrophied, and there was also a glossitis with pigmentation. Besides, the patients had diarrhea, epigastric distress, general weakness, vertigo, and a mental disorder. The disease appeared during the dry season when the food of these people consisted largely of whole millet, and this fact, combined with a failure to eat protein and foods containing vitamins A and D, and cholesterol, was considered responsible for the development of the disease. From a study of psychiatric problems in pellagra, Teglbjaerg, H P (*Acta psychiat et neurol* 9 195, 1934) believed the diets of the patients to be adequate, but on account of malabsorption from gastrointestinal disorders, the essential vitamin passed through the body. Treatment with a plant preparation, which contained most of the vitamins, brought about a prompt recovery. In patients with chronic diarrhea, Andie (*Wisconsin M J* 33 581, 1934) has pointed out the importance of considering pellagra. Of several patients with this disorder that came under his observation, one developed the disease as a result of an attempt to live on cheap staple food for some time, another as a result of substituting food for drink, and a third as a result of attempting to lose weight from the consumption of a very restricted diet.

In the treatment of pellagra, Wheeler, G A, and Hunt, D J (*Pub Health Rep* 49 732, 1934) have tried the effects of various foods on patients with this disease. On the basal diet persons developed pellagra in three to six months, but by the addition of 502 Gm of canned green onions or 516 Gm of canned green lettuce, daily, the appearance of the disease was delayed until eight to nine months, and by supplementary feedings of 200 Gm of lean pork or of peanut meal daily proved more effective, and the disease did not develop in twelve months. The treatment of pellagra with preparations of liver has been tried by Ruffin, J M, and Smith, D T (*Am J M Sc* 187 512, 1934). The patients were given a complete diet, except for vitamin G, and the skin lesions of few disappeared, but when exposed to the sunlight they recurred. Supplementary feedings of 90 ml of aqueous liver extract or of the powdered extract taken daily by mouth brought about a prompt recovery, but 5 ml of liver extract injected daily into the muscles proved valueless. In the treat-

ment of the disease, Spies, T D (*J Clin Investigation* 13 807, 1934) has tried feeding patients 250 to 800 Gm. of antoclaved liver daily, and without any other food found the month lesions were relieved in a few days. Other groups of patients have been kept on a pellagra producing diet after entering a hospital were then given 750 to 1000 Gm. of "ventriculin" orally or 80 ml of liver extract intravenously, and rapidly recovered.

A few patients with peripheral neuritis about the time of parturition have been observed by Sze, T S (*Chinese M J* 48 651, 1934). The cause of the disease was evidently the result of a custom carried on by mothers at this time by which vegetables are not consumed because the disorder was readily relieved by supplementary food rich in vitamin B. The effect of the keto genic diet on institutionalized patients with epilepsy has been studied by Notkin, J (*Arch Neurol & Psychiat* 31 787, 1934) and found valueless. Of the twenty patients to try the treatment, only two had fewer convulsions while in all of the others the number and severity of the convulsions were increased.

SCURVY AND SKIN DISEASES

The history of scurvy in the 17th and 18th Centuries has been compiled by Liddell E G T (*Nature* 133 67, 1934) and even in some of the earliest records of treatment the use of citrus fruit juices was described. Some of the lesions of scurvy in a few patients have been reported by Scheer, M., and Keil H (*Arch Dermat & Syph* 30 177, 1934). In these patients follicular lesions of the skin appeared but the small interstitial hemorrhages which sometimes formed dull red papules were more typical of perifollicular petechiae of scurvy. If these lesions were not evident in some parts of the skin, they were artificially produced by the use of a tourniquet but when treatment had been successful petechiae could not be artificially made. The necessity of observing the food consumed by insane patients to prevent deficiency diseases, has been pointed out by Barton W E and Freeman W (*New Eng J Med* 210 529, 1934). A patient is reported, who when not observed ate only meat and potatoes, and scurvy developed. The disease was relieved by the use of a more liberal diet, but again when not watched he ate as before, had an epigastric hemorrhage, and died. To test the efficacy of certain foods in the treatment of scurvy, Bonbrant, W W Jr (*Texas State J Med* 29 565, 1934) kept a patient on a scorbutic diet for twenty two days, then he was given 300 Gm of grapefruit, four oranges, and four lemons daily. The immediate effect of this food was to produce a marked diuresis, then the relief of the edema, and finally the reduction of the temperature to normal. The symptoms disappeared rapidly and the disease was relieved in a short time.

Observations on capillary resistance to determine a prescorbutic condition in children, have been applied by Greeno, D (*J A M A* 103 4, 1934). Of twenty three young children tested, five were found positive but of sixty five older children only six were found positive. Subsequent tests on these prescorbutic patients were variable, because in some of the children petechiae could be produced by a tourniquet on one arm but not on the other. Szent-Gyorgyi (*Deutsche med Wchnschr* 60 556, 1934) has described the prescorbutic state in children, and maintained that scurvy should be prevented. The use of 25 mg of ascorbic acid daily by infants was recommended. The titration of human serum with dichlorophenolindophenol to determine its vitamin C content has been carried out by Gabbe, E (*Klin Wchnschr* 13 1389, 1934). In ninety unselected patients the amount of vitamin C was found to be from 0.14 to 1.21 mg per cent, but in seriously ill patients it ranged from 0.50 to 0.69, and in others it was generally proportionate to the vitamin C content of the diet. This was demonstrated experimentally, for in a few patients the use of a vitamin C free diet for a week caused a lowering of the serum values that of a vitamin C rich diet produced high values while the administration of 90 mg of ascorbic acid daily for ten days, brought about a marked rise in the vitamin C content of the serum.

New principles of dietary treatment for psoriasis have been recommended by Grütz (*Deutsche med Wchnschr* 60 1039, 1934). In this treatment a disorder of fat metabolism was thought to cause the disease, and the restriction of 10 to 20 Gm of fat a day to sixteen severe psoriatics brought about relief after a month. An increase of fat in the diet above 20 Gm often caused a recurrence of the disease in these patients. A relation between the incidence of tropical ulcer and the food consumed by patients in New Guinea has been pointed out by Clements, F W (*M J Australia* 1 520, 1934). The incidence was found high in those that consumed food almost entirely composed of carbohydrate and with few vitamins it was intermediate in those that ate moderately of cereal food but some protein and vitamins, and the disease was not found in any that ate complete and well proportioned meals. The inferences drawn were that poor diets produced malnutrition of the skin and lowered vital resistance, as a result of which organisms entered the body to cause the ulcers. Pfister F F (*J A M A* 102 533, 1934) has reported the development of a skin rash in a few infants from the excessive use of cholesterol and to prove this assertion the oil was omitted and the rash disappeared, then it was resumed again and the rash returned. Longitudinal ridging and transverse depressions of the finger nails have been observed by White, C (*J A M A* 102 2176, 1934) in a group of women who ad

hered rigidly to a reducing diet. And the administration of a liberal and complete diet, haliver oil, or viosterol, brought about a more normal condition of the nails after some time.

PICKETS, OSTEOMALACIA, AND DENTAL DECAY

In a search for patients with rickets in Porto Rico by Ehot (Bull No 217, U S Dept Labor, Child Bureau, 1933) only a few were found, and in spite of the fact that the people generally consumed food lacking in vegetables and milk. Many patients with osteoporosis however were found, and this was evidently the result of gross general inadequacies, and especially of a deficiency of calcium, in the food. The rarity of rickets was ascribed to the therapeutic effects of the continual and intense sunshine. The severer forms of rickets have become less common of late in comparison with the period before the general administration of vitamin D, according to the report of Mader and Eckhard (*Arch f Hyg* 111 362, 1934). The prevention of such extreme malnutrition has had other beneficial results, inasmuch as the fatal complications of whooping cough or measles which often followed this condition have been averted. Other factors may serve to enhance the value of vitamin D in the treatment of rickets in children. At all events, Wieland, E (*Ztschr f Kinderh* 56 19, 1934) has observed that healing began in a patient with active rickets, then ceased in spite of the continued use of irradiated milk and a high blood calcium. Whereupon, the diet was changed from one largely composed of cereal food and milk to one of vegetables and fruit. With the change of food healing began again, and continued without the use of the antirachitic measures. In a comparison of the various methods of treating rickets in children, Hay, J R W (*Lancet* 1 1390, 1934) has found, that a daily exposure to the carbon arc lamp produced healing in four to eight weeks, that a drachm of cod-liver oil brought about the same result in six weeks, but two commercial preparations of ergosterol were almost ineffective in five to eight weeks of treatment. Degkwitz, R (*Klin Wchnsch* 13 201, 1934) has expounded a theory on the pathogenesis of rickets, by which vitamin D mobilizes the phosphorus from the tissues into the blood stream, and also regulates Ca and P metabolism by facilitating the formation of compounds of these elements and their deposition in growing cartilage.

The symptoms of hypervitaminosis D have been described by Reed, C I (*J A M A* 102 1745, 1934). Several hundred patients with asthma, parathyroid tetany, and hay fever, were given excessive doses of viosterol. Frequent micturition was found to be the commonest initial symptom, then loss of appetite, nausea, vomiting, diarrhea, muscular weakness, disturbed equilibrium, and loss of weight, were some of the other symptoms produced. The

amount of viosterol that could be taken by a patient daily, and for an indefinite period, was estimated at 150,000 international units. In a somewhat similar study, Hansman, F S (*M J Australia* 1 81, 1934) has observed the effects of large doses of vitamin D on a few patients with combined hyperthyroidism and hyperparathyroidism. The results obtained were that the symptoms of the latter disorder rapidly disappeared, but there was little change in the amounts of Ca and P, and only a slight improvement in their balance, in the blood. On this account, vitamin D was believed to act by making Ca available for tissue metabolism. From a study of hypervitaminosis D in rats, Ham, A. W., and Lewis, M. D (*Brit J Exper Path* 15 228, 1934) observed that rachitic lesions were still apparent in the long bones of these animals after three weeks of treatment. The conclusion reached was that large amounts of vitamin D inhibited the normal process of calcification in bone.

An authoritative and comprehensive account of "Osteomalacia and Diet" has been written by Maxwell, J. P. (*Nutrit Abs & Rev* 4 1, 1934). The disease was found to be most prevalent in China and India, and generally afflicted the women of these countries. The food of the Chinese was not only inadequate, with an average of 1188 cal, of which 39.3 Gm were protein, 22 Gm were fat, and 212 Gm were carbohydrate per man per day, but also very low in foods containing the vitamins, calcium, and phosphorus. The food of the East Indians was not very different, inasmuch as cereal food was largely consumed, and only a little meat, eggs, and milk were added, and few vegetables and fruits partaken of. Here too, the seclusion of the women indoors was a factor in the development of the disease, for when they were allowed fresh air and sunshine, a good diet, cod-liver oil, and calcium, a rapid cure was effected. In a postmortem examination of a patient dying of osteomalacia, Gunn, F. D., and Nadler, W. H. (*Arch Int Med* 54 145, 1934) not only found typical skeletal defects, but also a hypertrophy and hyperplasia of the parathyroid gland, hypertrophy of the hypophysis, and calcareous deposits in the kidneys. A patient with intestinal disturbances, which evidently caused osteoporosis and spontaneous fractures, has been reported by Wendt, H. (*Med Klin* 30 187, 1934). The patient, a woman of thirty-nine years, was found to have normal biliary and pancreatic secretions, but the resorption of proteins, fats, and carbohydrates, was greatly reduced, and the calcium and phosphorus in the blood were diminished.

A comparison between the incidence of dental decay and malnutrition in uncivilized and semi-civilized peoples of the Alaskan peninsula has been made by Price (*J Dent Res* 14 227, 1934). The amount of decay found in the Eskimos of W. Alaska was only 0.09 per cent,

that of isolated Indians was 0.16 per cent, whereas that of the natives living in the more populated districts, was 13.0 and 21.5 per cent. The difference in the diets was a marked increase in the amount of food consumed in proportion to the mineral matter, and a marked decrease in the amount of the fat soluble vitamins, for those in contact with civilization. On a basis of 3000 cal a day, the Eskimo or the Indian consumed 2.14 Gm of Ca, 5.7 of P, 0.1 of Fe, 1.27 of Mg, 0.0312 of Cu, and 0.000131 of I, whereas the native eating many foods of white flour and sugar, consumed only 0.39 Gm of Ca, 1.14 of P, 0.067 of Fe, 0.16 of Mg, 0.0167 of Cu, and 0.00000276 of I. In a comparison of the incidence of dental hypoplasia and caries and of rickets, Eliot, M. M., et al (*Am J Dis Child* 48 713, 1934) have found some interesting correlations. These investigators had an opportunity to make dental examination on a group of 450 children, whom they had examined four years earlier for rickets, and found that 15 per cent had hypoplasia of the enamel and especially in those who had severe rickets previously, and 53 per cent had caries, which however was not related in any way to the previous deficiency disease. A valuable study of dental decay, as an indication of malnutrition, has been made by Larsen, N. P., et al (*Am J Dis Child* 48 1228, 1934). In this study, groups of young children were fed for a period of a year or more on (1) milk from rice eating mothers and rice, (2) cow's milk, rice, and a few eggs and vegetables, and (3) milk with poi, potatoes, and other vegetables. The composition of the diets was much the same, the chief difference being in the reaction, for the first was neutral the second 6 to 10 ml basic, while the third was 40 to 45 ml basic. At the end of the period of observation, the children given the third diet were found to average two pounds heavier and one inch taller than those consuming the other diets. A more striking correlation however was found in the incidence of dental decay, for those on the predominantly basic diet had only 7 per cent, whereas those on the slightly basic diet had 50 per cent, and those on the neutral diet had 46 per cent, of carious teeth. A low incidence of caries was found in children living in an institution, by Koehne, M., and Bunting, R. W. (*J Nutrition* 7 657, 1934). On the presumption that the food consumed was responsible, it was analyzed and found to be of a low calorie value, and with little Ca and P, but the meals were regular, generally uniform in composition, and contained little sweet stuff, and these were the factors that contributed to good nutrition and health.

In "Dental Health a Problem of Nutrition", Garland Joseph (*New Eng J Med* 210 563 1934) has maintained that adherence to a sin-

gle cause of dental caries in children may be misleading, and that consideration should be given to the consumption of foods for the construction of tissue, the production of energy, and the preservation of health. A basic diet, consisting of a quart of milk, eight ounces of orange juice, a pound of vegetables, one or more eggs and a little meat, were recommended for daily consumption by a growing child. The assertion has been made by Fox, F. W. (*South African M J* 8 517, 1934) that races living on food rich in minerals have sound teeth but that the food of civilized races was generally low in these essential substances. Diets high in minerals have been found valuable in arresting caries, and while Ca and P retention may be reduced in patients with this disorder, other changes in the mineral metabolism were not apparent.

ANEMIA AND THE METABOLISM OF PROTEIN

The anemia of premature infants has been studied by Thoenes, F. (*Klin Wochenschr* 13 658, 1934) and called physiological, for comparatively large doses of iron or liver given these patients were found valueless. On this account, the disorder was considered due to a faulty fetal metabolism, which might be prevented or corrected only under interuterine conditions. In observations on the anemias of children Hawley, J. O. et al (*Arch Dis Child* 9 359, 1934) often found achlorhydria, and this continued to be present in a few of these patients for a year or more after the anemia had been cured by iron. Then too they frequently found hypochromic anemia in children who had severe intestinal disorders, such as ulcerative colitis, celiac disease, or polyps of the intestine, which generally caused a small but constant loss of blood. Mettler, S. R. and Kellogg, F. (*J Clin Investigation* 13 715, 1934) have made a comparison between the use of inorganic iron and predigested meals, in the treatment of patients with hypochromic anemia. The meals composed of beef eggs and spinach, were predigested with pepsin and HCl, and were of the same pH value but only one half the iron content as the ferrous salts. The meals alone were found to have a curative effect on the anemia. The anemia of pregnancy has been studied by Strauss, M. B. (*J A M A* 102 281, 1934). Of the thirty patients with the hypochromic type observed the majority had consumed food of a low iron content for years and in examinations of the gastric contents, only two were found to have normal hydrochloric acid. Treatment with iron brought prompt relief. And of ten patients with the pernicious type half had none, and the remainder, little hydrochloric acid, thus, the disease was considered due to the temporary loss of the intrinsic factor in the gastric secretion.

and treatment with liver brought about prompt regeneration of the blood

Interesting and significant structural changes found in the tissues of 151 patients who had had pernicious anemia, have been described by Brown, M. R. (*New Eng J Med* 210 473, 1934) from postmortem examinations. Of this number, eighty-two showed gross lesions of the gastrointestinal tract, and forty-two histological preparations of the stomach all but one showed a chronic gastritis, and all but four the absence of acidophilic cells. The deductions drawn were that "interference with the normal motility of the gastrointestinal tract over a long period of time may give rise first, to inadequate digestion, and secondly to atrophic gastritis and inadequate gastric juice." The racial factor in the development of pernicious anemia has been described by Friedlander, R. D. (*Am J M Sc* 187 634, 1934) from a study of 500 patients, and in those living in temperate zones and of fair complexion, the disease was found to occur most frequently. Stub, O. (*Acta med Scandinav* 81 535, 1934) has analyzed the mortality statistics of pernicious anemia in the fishing districts of Norway, and reported a very low rate. The result was ascribed to the very general consumption of cod livers and cod-liver oil, by the people living in these districts. Several peculiar observations on the action of the gastric glands in patients with pernicious anemia have been reported recently. In one Lassen, H. C. A. (*Acta med Scandinav* 82 588, 1934) described a woman of sixty-one who became free of the disease and had kept well for nine years, although examinations of the gastric contents only once revealed the presence of free hydrochloric acid. In another Alsted, G. (*Acta med Scandinav* 82 288, 1934) wrote of a woman of sixty-seven who had the disease and achlorhydria, but with liver therapy the blood became normal, and several months afterward gastric analyses revealed the presence of free hydrochloric acid.

The best and cheapest method to treat patients with pernicious anemia, according to the observations of Franke, Y. (*Klin Wchnsch* 13 127, 1934) was by the use of liver juice acted on by gastric juice *in vitro*, and administered through a duodenal tube. And to prevent relapses, the injection of 5 to 10 ml of liver extract with 3 Gm of reduced iron daily, was recommended. A somewhat similar preparation for the treatment of this disease has been described by Reimann, F., and Fritsch, F. (*Klin Wchnsch* 13 951, 1934) and was made by incubating liver with normal gastric juice or an extract of the gastric mucosa of the pig, and hydrochloric acid. This preparation was found very potent, as 10 to 20 Gm produced the same regeneration of corpuscles as 250 to 300 Gm of raw liver, in the treatment of the

disease. A marked variation in the digestion and hydrolysis of beef protein in the human stomach has been reported by Maltby, E. J. (*J Clin Investigation* 13 193, 1934). Variations were not only found in the hydrolysis of this food in the stomach of healthy persons from time to time, but also in the same person at different times, and in the stomach of patients with pernicious anemia, little or no hydrolysis occurred. In the gastric contents of these patients too, pepsin as well as hydrochloric acid was generally absent. In the treatment of the disease by liver acted on by the gastric juice Conner, H. M. (*M Clin North America* 18 385, 1934) has obtained beneficial results, but not any more so than other kinds of liver therapy. The new form of liver treatment, however, was found valueless in patients with sprue.

From a study of tropical sprue, Farley, N. H. (*Brit M J* 2 1192, 1934) believed the disease to originate from a failure in the functions of the gastrointestinal tract. As a result, thirty-three patients were required to rest and were given a high protein but low fat and carbohydrate diet, and liver extract as indicated for the anemia. Beneficial results were generally obtained, but the very rapid regeneration of corpuscles some times produced a hypochromic anemia which required treatment with iron. The potency of preparations of liver from various domestic animals, to cure experimental anemia in dogs, has been estimated by Robscheit-Robbins, F. S., and Whipple, G. H. (*Am J Physiol* 108 279, 1934). On the assumption that pig's liver was 100 per cent potent, beef liver was found to be 70, rabbit 80, reindeer 90, and horse and fetal calf 124 per cent. The potency of livers from lactating animals for this purpose was reduced. In other observations by the authors (*Ibid* 108 270, 1934), the liver of a horse made anemic by bleeding was as potent to regenerate corpuscles, as a normal horse's liver, but one from a horse made anemic by injections of a toxin was very impotent, and the iron content of both livers was much reduced. As gastrectomized dogs do not develop pernicious anemia, Ivy, A. C., et al. (*Am J Digest Dis & Nutrition* 1 116, 1934) have tried the effect of preparations of dog's stomach on patients with pernicious anemia. These preparations however proved of little value, for they were found to be half as potent in the treatment of the disease as those of hog's stomach. And an extract of liver from the dog had only one fourth the potency of that from the hog, steer, or horse, but when canine liver was administered orally it proved to be one half the potency of bovine liver. The results suggested, that the "intrinsic factor" of Castle is present in the intestine as well as the stomach, or that the dog, pig, and rat, are so constituted that they cannot develop pernicious anemia, or that factors besides the "intrinsic factor" are involved in the genesis of the disease.

DIABETES MELLITUS, OBESITY, AND THE
METABOLISM OF FAT

A detailed description of the treatment of severe diabetes in children has been given by Cole, L (*Lancet*, 1 947, 1934). In the treatment the chief consideration was the allowance of food to provide for the growth of the child as well as fulfill the energy requirements. For this purpose about 100 Gm of carbohydrate was allowed daily in severe cases and up to 200 Gm if the disease was mild. Insulin was administered to keep the sugar in the blood within normal limits generally. Satisfactory growth, activity, and mental and sexual development, were brought about by this treatment. On the other hand Soderling (*Nord med tidsskr* 8 1021, 1934) has recommended the free choice of food for diabetic children because the restricted diet had a psychic effect on the patients, and was likely to disturb carbohydrate metabolism. In practice this principle worked well, for only in the period of readjustment was there a slight and temporary overindulgence in carbohydrate food and only in a few instances was the amount of insulin increased. A diet for diabetic children from two to ten advocated by Stewart (*J Amer Dietetic Assn* 10 238, 1934) consisted of 5.1 Gm. of carbohydrate, 2.9 Gm of protein and 4.1 Gm of fat, daily, per kg of body weight. Calcium and the vitamins were supplied in 600 cc of milk, 30 Gm. of cheese and 450 to 600 Gm. of vegetables and fruit given daily to these patients.

The complete diets now used in the treatment of adult diabetics, according to Nixon, J. A. (*Practitioner* 132 25, 1934) may require the administration of more insulin, but the psychological effect produced in the patients by the more liberal selection of food, more than offset the effects of increased medication in the successful treatment of the disease. Test meals of the same sugar content and consisting of 600

Gm. of apples, of a mixture of dextrose, levulose, and saccharose, of dextrose, and of levulose have been given patients with diabetes obesity, and liver disease, by Deindl, A. (*Deutsches Arch f Klin Med* 176 311, 1934). The blood sugar curves produced in all of the patients were very similar, and thus proved the similarity between these diseases. Then, as the curve of the apple meal was not so high, and also was slower to return to normal compared with those of the pure sugars, it demonstrated the unfavorable influence the ingestion of fruit had on diabetes and similar diseases.

From a study of obesity in childhood Ellis, R. W. B., and Tallerman, K. H. (*Lancet* 2 615, 1934) recommended that dietetic restrictions should be carried out only when the disease gave rise to symptoms, and even then should not be severe and interfere with normal growth and development. Ambulatory obese patients were put on a daily diet of 680 cal, of which 85 Gm were protein, and 40 Gm each of fat and carbohydrate, and observed by Beck, E. C., and Hubbard, R. S. (*Am J Digest Dis & Nutrition* 1 250, 1934). The food consisted largely of meat, eggs, cheese, broths, and green vegetables, and was selected on account of its satiety value. The diet brought about an average loss of almost two pounds a week for the first two months and about one pound a week afterward, and the original symptoms of dyspnea, inertia, edema and hypertension were generally relieved, but dizziness was unaffected. The relation between the composition of the fat consumed and that excreted by man, has been studied by Krakower, A. (*Am J Physiol* 107 49, 1934). In meals which contained a large, and in those which contained a small amount of fat, a significant change was not found in the feces, therefore, an excess of fat in the feces may be due to the discharge of this substance from the blood into the intestines, rather than to the ingestion of a large amount of fat food.

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL-PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C CABOT, M.D

TRACY B MALLORY, M.D., *Editor*

CASE 21361

PRESENTATION OF CASE

First Admission A thirty-five year old American housewife entered complaining of epigastric pain

Approximately seventeen years before entry, while convalescing from an operation at which a cervical rib was removed, she had an attack of severe boring epigastric pain which was accompanied by nausea and vomiting. The pain slowly disappeared in about two days but the region was tender for about a week. These attacks recurred, at first about every two years and more recently about once every month, with or without jaundice. Three years before entry a gall bladder filled with many small stones was removed at another hospital. She felt well for six months following the operation and then began having attacks of chills and fever, associated with indigestion. At first there was no pain but after two or three attacks the pain was the same as had been present previous to operation—a dull, heavy, boring epigastric pain which radiated to the shoulder. She was treated with a duodenal tube for sixteen months without relief. The pain often required a hypodermic injection of morphin and often lasted several hours. Between attacks she felt quite well. During each attack she became jaundiced, her urine was very dark and her stools, which were always light colored, frequently became clay colored. Her appetite was always good and she had gained about five or six pounds since the operation.

Her family, marital and past histories are non-contributory.

Physical examination showed a well-developed and nourished woman with slightly icteric skin. The heart and lungs were negative. The abdomen was negative except for a right rectus splitting upper abdominal scar. No masses were felt. There was no tenderness.

The temperature was 98°, the pulse 85. The respirations were 20.

The urine was amber colored and gave a one plus bile test. Examination of the blood showed a red cell count of 3,500,000, with a hemoglobin of 80 per cent. The white cell count was 8,200. An icteric index was 15. The bleeding

time was two minutes, the clotting time ten minutes.

Exploration of the common bile duct, with drainage, was performed. At operation a lymph gland approximately 1.5 by 1 by 1 centimeter was found lying on top of the common duct. This gland and two smaller ones were removed and it was felt that these might be causing the constriction of the duct. The duct was opened and a probe passed easily down into the duodenum. It went upward only as far as the level of the cystic duct. Little or no bile came out of the duct when it was opened. She did well postoperatively and was discharged approximately three weeks after operation.

Second Admission, approximately seven years later.

Ten weeks after discharge, because of return of the same symptoms, she entered another hospital where a choledochoduodenostomy was performed. She did fairly well postoperatively for about a year and then had recurrence of her former attacks of chills, fever, sweating, jaundice and occasional right upper quadrant pain. About a year and a half after the anastomosis another operation was performed, at which time the hepatic duct as it opened into the duodenum was dilated. Shortly after the operation her symptoms recurred and she had right upper quadrant pain similar to that which preceded her first operation. There was also severe itching of the skin and jaundice.

Physical examination showed a somewhat undernourished, jaundiced woman. The heart and lungs were negative and, except for the operative scar, the abdomen was also negative.

The urine was dark amber colored and had a specific gravity of 1.012 to 1.024, a slight trace of albumin and a plus one test for bile. The blood showed a red cell count of 3,460,000, with a hemoglobin of 60 per cent. The white cell count was 25,000, 91 per cent polymorphonuclears. The icteric index was 35. The bleeding time was two and a half minutes, the clotting time eight minutes.

The temperature was 102°, the pulse 95. The respirations were 22.

On the third day an exploratory laparotomy was performed. She did poorly following operation and developed chills and fever, 104°. She received several transfusions.

X-ray examination of the chest on the fourteenth postoperative day showed numerous fairly sharply outlined, irregular areas of mottled dullness in both lungs.

She gradually failed and died on the eighteenth postoperative day.

DIFFERENTIAL DIAGNOSIS

DR. GEORGE A. LELAND. The only comment we would make about the opening sentence is that one should not have in mind a thirty-five year old patient, one should have in mind a

forty-two year old patient because the second admission is seven years later.

It appears that the patient had a cervical rib removed when she was eighteen years old. It does not say which side the rib was on. If we can assume that it was on the right side and was removed for pain in the right shoulder possibly the pain was due to biliary disease, with irritation of the diaphragm. It is of some significance that she began to have this boring pain very shortly after the operation on the cervical rib. Whether or not the rib was removed on account of pain from biliary disease the fact remains that these attacks which from her eighteenth year up to the time she was thirty-five occurred every two years, came on with or without jaundice. Then she had a second operation when she was about thirty-two years of age. At that time a gall bladder filled with many small stones was removed at another hospital.

"She felt well for six months following the operation and then began to have attacks of chills and fever associated with indigestion." That story would seem to indicate several possibilities. If we can assume that she had been having biliary tract disease for a number of years before her gall bladder was removed she probably had by this time developed a damaged liver, with some degree of biliary cirrhosis. And then having had more trouble six months after operation might mean that she had some stones present in the common duct or the hepatic ducts that were overlooked at the time of the first operation or it might mean that she was beginning to develop a stricture in her common duct. Stricture from cicatricial contraction not infrequently comes along about six months after removal of the gall bladder. I mean by that if a stricture is forming symptoms may not occur until five months have elapsed. Such a stricture may be due to trauma at the time of operation to actual ligation of the common duct with the cystic duct and perhaps in some instances to interference of the blood supply when the cystic artery is clamped or when the dissection is being made around the stump of the cystic duct. We cannot tell up to this point whether her recent attacks were due to cicatricial stricture or to stones.

"The recurrence of the boring epigastric pain radiating to the shoulder" brings us back to the question of why the cervical rib was removed.

The pain was relieved by morphia. Pain that requires morphia, severe pain, suggests a colicky type of pain and suggests a common duct type of colic which might be an endeavor to push along a stone or to get bile through a stricture.

These attacks showed definite obstruction jaundice, changes in the urine and stools. In spite of these many attacks, however she gained

a little weight. That is because she was in the upswing of life—she was going up to thirty-five years and had the resilience of youth that carried her along in spite of the attacks of indigestion.

The rest of the laboratory tests suggest biliary obstruction, a one plus bile test, an icteric index of 15, bleeding time of two minutes and clotting time of ten minutes. The blood picture is reasonably satisfactory, 3,500,000 red cells, with a hemoglobin of 80 per cent, and shows no evidence of infection at this time, the white count being 8,000. This story is so consistent with obstruction of the common duct that it was quite reasonable that an exploration with endeavor to free up or promote drainage through the common duct was apparently advised and undertaken. Here is the third operation the patient has had. She is only thirty-five years of age.

It was apparently felt at this operation that these lymph nodes were playing a part in constricting the duct. That would indicate by inference that she did have a constricted and not a dilated duct in its lower portion. The record does not state that these lymph nodes were hard. They are not described as being suggestive of malignant disease in that respect. I think it is debatable as to whether lymph nodes in that region can really seriously constrict the duct unless they are involved in some malignant or acutely inflamed process. Their presence would be more indicative perhaps of some chronic inflammatory condition in that vicinity. Dr. Deaver used to talk about pancreatico lymphangitis and was known to make that diagnosis when he found enlarged lymph nodes in the absence of other definite pathology in that region. I do not know whether that diagnosis is of importance here but these lymph glands when found usually do mean some evidence of chronic inflammation.

The level of the cystic duct is about the place one would expect to find stricture following cholecystectomy and about the place one would expect to find primary malignancy of the bile duct if one was anticipating that possibility. The record does not indicate whether there was any so-called white bile or mucus. It only intimates that there was a constriction at the level of the cystic duct.

It does not say whether there was any bile coming out of the abdomen during the three weeks after operation. It rather suggests that perhaps there was not. Three weeks is the approximate time for a patient to go home following a cholecystectomy. If the case has a draining biliary sinus of consequence following a choledochostomy three weeks would be a fairly short time.

Dr. TRACY B. MALLORY. There was drain age of five to eight ounces for the first week.

DR. LELAND The patient went home with the hope that the removal of the glands might be of consequence in relieving this constriction of the duct. There is no intimation from the record that any attempt was made to explore the constriction or to relieve it except by removal of the lymph nodes. There is also no note made to indicate that there was any dilatation of the common or hepatic ducts above the constriction.

Then we jump to the second admission approximately seven years later, when she was forty-two, but you will note that ten weeks after discharge from the hospital following the lymph node operation because of return of the same symptoms she entered another hospital where operation was performed. When she was operated on at her first admission she was thirty-five, that is when the lymph nodes were removed. Just ten weeks after discharge she was operated on at another hospital. At that operation anastomosis was done between the common duct and the duodenum. That would seem to indicate that perhaps the common duct was found to be dilated at this other hospital. She did well for a year and then had recurrence of former attacks. We would interpret that as meaning that the stump between the common duct and the duodenum was beginning to contract and that a stricture was forming in the stoma. This is a very frequent possibility and should be provided against by making a very wide opening in the duodenum, wider than the diameter of the duct. Sometimes the operation is performed close to the liver and hepatic ducts, the so-called Mayo hepatico-duodenostomy.

"About a year and half after the anastomosis another operation was performed." That makes the fifth operation, fourth on the biliary system, and brings her to about the age of thirty-six or thirty-seven. Dilatation through the duodenum of such a stoma cannot be expected to be of very permanent value. One should anticipate the likelihood of its closing down again. The stricture is not similar to a urethral stricture in which dilatation may be of value over some period of time.

We now arrive after this long past history at the physical examination at her second admission. It is to be noted that at the age of forty-two she is a somewhat undernourished jaundiced woman as compared to "well developed and nourished woman" at the first admission. The heart and lungs are still negative. Except for the operative scar the abdomen is still negative.

This presents quite a different picture from her first entry. We know that she has had up to this moment four operations on her biliary tract. We know that she had stones and we know that she has a constricted common duct. The constriction can be perfectly well account-

ed for by adhesions, an inflammatory reaction, and we do not have to go into the realm of malignant disease to account for this constriction. It seems unreasonable to suppose that she would have malignant disease over this period of time. Certainly the start of her trouble was inflammatory and not malignant. I can well imagine the hopeless feeling the surgeon must have had, confronted with such a problem as this. Here was an individual who in spite of repeated operations on her biliary tract was showing more and more insufficiency of liver function, more and more damage by her repeated attacks, and she finally reached the point where chills and fever were recurring. Her blood showed loss of hemoglobin, anemia, and high icteric index. I should imagine that the surgeon would have thought that he was going in with the hope of opening up some dilated portion of the bile ducts in an effort to give external drainage through a sinus with some temporary relief from her immediate acute symptoms, and with perhaps a background of hope that later on that sinus might be retransplanted to make a new duct. On the other hand he may have felt that during this course of time there was more than inflammatory reaction and some degree of malignancy had intervened. I should think that unlikely, however.

"On the third day an exploratory operation was performed." That makes the sixth operation this patient has had, fifth on the biliary tract. We can understand the chills and fever—undoubtedly infection throughout the liver with pyelophlebitis. We might reasonably well expect that. The transfusion may have been indicated by some degree of local hemorrhage, with the increased clotting time and high icteric index, perhaps that is why the surgeon was unable to give her a satisfactory vent for her biliary drainage.

It would seem that with an x-ray taken at this time they were hardly looking for malignant disease. She must have had some pulmonary complication. Although it is difficult to visualize an x-ray from a written description we should think that probably the irregular areas of mottled dullness were septic infarcts.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES These are films taken at the bedside and give a rather different impression from what one gets on reading the note. They are not at all characteristic of the nodules one would expect to see in metastatic carcinoma or metastatic tumor of any kind. The process seems to be largely confined to the left lower lobe. There is an indefinite area of dullness which occupies the periphery of that region and there are areas of increased density, sharp and distinct, which look more like infarcts, thrombosis or even metastatic abscesses than like tumor. The diaphragm is high on both sides and the heart is a little enlarged. I

am rather surprised that no search was made earlier for possible stones in some part of the biliary tract.

DIFFERENTIAL DIAGNOSIS CONTINUED

DR. LELAND That leaves us with a chest picture which corroborates the idea that we have a definite infection in the liver with a biliary cirrhosis. I do not think we would expect to find, with pyelephlebitis and benign stricture of the bile ducts, that there are stones lurking up in the liver or bile ducts. We have no way of knowing. There may be sand, there may be some stones. Stones, if found, probably had been left behind at the original operation and added to in the course of time rather than having been actually formed there. I do not think we have to depend on stones for the picture. I think this patient died from cicatricial stricture of the common duct starting well back at the time of the first operation when she was thirty-two years of age.

CLINICAL DISCUSSION

DR. DANIEL FISKE JONES Dr. Leland was quite right when he said we were disturbed about this patient. Here is a patient operated upon for gall stones and a cholecystectomy done. Six months later she began to have attacks of chills, fever and jaundice. It may be well to note here that stricture of the common duct occasionally follows cholecystectomy and that stricture may cause the same symptoms as a stone in the common duct. Another point to be noted is that pain in the shoulder such as this patient had is much more frequently noted with distention of the liver due to obstruction in the common duct than with distention of the gall bladder. This was demonstrated in a patient with multiple abscesses of the liver, operated upon under local anesthesia. The only discomfort the patient had during the operation was at the time the finger was put into the liver to break up an abscess. At that time the patient complained bitterly of pain in the right shoulder blade.

At the second operation, which was in this hospital, two moderately enlarged inflammatory glands were found in close contact with the duct, but no stones were found. A probe could not be passed upward above the region of the cystic duct. It was thought that the glands might be the cause of shutting off the common duct. In regard to this I may say that I have never seen any gland or mass other than malignant disease shutting off the common duct. I should like to ask Dr. Mallory if he has ever seen anything outside the duct other than malignant disease causing obstruction to the common duct.

DR. THOMAS B. MALLORY It has been reported with tuberculosis

Dr. JONES It must be very rare as I have never seen obstruction due to anything outside the duct, other than malignant disease, in about two thousand cases. This does not mean that it does not occur but it must be very rare.

The stricture found at the second operation, for which nothing was done, did not cause symptoms for nearly six months after the first operation, a little late, but of course, as Dr. Leland says, the stricture would naturally contract for some time after the injury to the duct. We could not say, therefore, that the symptoms could not be due to the stricture.

At the third operation, ten weeks after the second, again no stones were found, but there was a stricture in the region of the cystic duct, the usual location of a stricture due to injury to the duct at the time of operation, and the duct above was dilated. The common duct was cut off above the stricture and the stump sutured to the duodenum by a method recommended by William Mayo. The posterior edge of the duct was sutured to the posterior edge of the opening in the duodenum. The anterior edge of the opening in the duodenum was then sutured to the surface of the liver about the duct. This leaves the anterior edge of the duct free and, as Dr. Leland has said, this edge may contract and cause a stricture.

As the symptoms recurred about a year after the third operation, a fourth operation was done because of the fear of a stricture of the duct. Again no stones were found and only a moderate narrowing of the duct was found.

The patient then went from January 1929 with infrequent attacks of chills fever and jaundice until April 1935, when she had a series of attacks extending over a period of two weeks. During this period of nearly six and a half years she had gained weight and had done very well in spite of the history which says that she was undernourished.

Again the duodenum was opened and the anastomosis found to be over one quarter of an inch in diameter. A probe was easily put into both the right and left hepatic ducts. The anastomosis was dilated to a number nine dilator, that is, nearly three eighths of an inch in diameter. Long forceps were introduced and a considerable quantity of fragments of stone, detritus and pus was withdrawn. This was continued for some time and then the duct gently washed through a small catheter until the water came back clear. As there was no way of draining the ducts except through a tube through the opening in the duodenum, it was decided to close the duodenum.

After the operation the chills, fever and jaundice continued until death. I do not agree with the record presented which says that she did poorly following the operation and developed chills and fever, for she had them when she came in and continued to have them after the operation.

This brings up the question as to what could have been done at the time of operation to give better drainage to the biliary system. With a wide open anastomosis between the common duct and the duodenum and no way of draining the common duct above the anastomosis without fear of leakage of duodenal contents, nothing seemed possible and nothing was done.

Medically nothing seemed feasible. Dr. Chester Jones saw her and suggested decholin but no effect was noted.

The question is as to what can be done for such a case. We know she had a stricture with infection of the biliary system above it for several years. We also know that she had an anastomosis between the upper end of the common duct and the duodenum without any sphincter such as the sphincter of Oddi. We believed that the repeated chills, fever and jaundice after the relief of the stricture were due to the backing up of duodenal contents into the biliary system and that I believe is the cause of the condition found at the last operation. At least this has been found to be the cause in experimental work on animals.

After the operation I began to consider what might be done to relieve this condition. It seemed possible that closure of the pylorus and a gastro-enterostomy might be of some value, but as the patient failed rapidly nothing could be done.

CLINICAL DIAGNOSIS

Cholangitis with biliary cirrhosis

DR. GEORGE A. LELAND'S DIAGNOSES

Stricture of the common duct

Biliary cirrhosis of the liver

Pylephlebitis

Septic infarcts of both lungs

ANATOMIC DIAGNOSES

Stricture of common bile duct

Cholangitis, acute and chronic

Biliary cirrhosis

Intrahepatic pylephlebitis, right lobe of liver

Pulmonary infarcts, septic

Operative wounds, Cholecystectomy, choledochoduodenostomy

PATHOLOGIC DISCUSSION

DR. MALLORY: Some of the questions raised by Dr. Leland and Dr. Jones can be easily answered. Others are much more difficult, and we were not helped at all by the restrictions of the autopsy which only permitted us to reopen the surgical incision and did not allow us to remove the organs.

The common bile duct was readily traced upward from the papilla of Vater for a distance of 3.5 cm. There it became completely ob-

structed by a dense fibrous scar, confirming Dr. Jones' presumption that the obstruction which followed the first operation was due to stricture rather than the pressure of any neighboring lymph nodes. The anastomosis of the remnants of the hepatic duct to the duodenum appeared to be in good condition and the stoma, as Dr. Jones found in his last exploration, was of adequate size. A large probe could easily be passed up into each hepatic duct without meeting any obstruction. To pass it into the right duct, however, it was necessary to go around an angle, whereas the left hepatic duct drained directly into the duodenum without angulation. Obstruction, if present at all, cannot have been of any great degree.

There was, however, a marked difference in the condition of the two lobes of the liver. The left was normal in size, very finely granular, slightly greenish and tougher than normal, the bile ducts slightly dilated—in other words the typical appearance of the mild biliary cirrhosis which seven years of intermittent bile-duct obstruction would lead us to expect. The right lobe, by contrast, appeared swollen, was soft and friable, and in fact ruptured during manipulation. On section the ducts were distinctly more dilated, containing frank pus, but no large abscesses were found. It appeared to be a typical enough diffuse cholangitis.

Microscopic examination did not entirely confirm this impression. There is an underlying diffuse biliary cirrhosis, evidently a long-standing process. Then there are more acute infectious lesions in the larger portal areas, but few of these involve the bile ducts, whereas many of them certainly lie in or about the radicles of the portal vein. In other words we have an intrahepatic pylephlebitis limited to one lobe of the liver. I have twice before been completely fooled by the gross examination, as we were this time, into believing that we were dealing with a pure cholangitis. Under the circumstances no amount of drainage of the biliary tree could have been effective.

The final complication was the development of several septic infarcts in the base of each lung which were well on their way to abscess formation.

CASE 21362

PRESENTATION OF CASE

The patient, a seven year old native born boy, was admitted to the hospital complaining of difficulty in swallowing.

One week before entry the boy was walking over an uneven sidewalk and lost his balance, falling over backward and striking the back of his head on a stone without losing consciousness. The following morning he complained

of pain over his eyes and soreness of the legs. He was drowsy, had no appetite and was apathetic. He vomited that night. For the next two days the child felt well. Three days before entry he awoke complaining of a severe headache and "weakness" of the legs. A physician saw the boy that night and found his neck to be slightly stiff. The patient took liquids but felt unable to swallow solids. The next day his condition was the same. On the day before admission he had greater difficulty in swallowing and liquids were taken only with considerable effort. There was a distinct change in the quality of his speech. He was very restless and feverish. The next morning he was more restless and seemed more seriously ill and was therefore brought to the Emergency Ward.

The child was delivered normally at term. His development was normal. His health had been satisfactory although he was considered "the delicate child of the family." He had had mumps and chickenpox. He had been subject to frequent colds and had had a tonsillectomy and adenoidectomy in 1927. His activity was less than that of his siblings. He had been vaccinated and was Schick negative following three doses of diphtheria toxin antitoxin.

There were four siblings, all living and well. There was a definite history of tuberculosis in the mother's family with some contact. The father had a mild diabetes.

Physical examination showed a well developed and nourished boy who was acutely ill, restless when disturbed and drowsy when left alone. His cheeks were flushed, his eyes bright. His skin and mucous membranes were moderately dehydrated. He talked with a nasal twang which was difficult to understand. The pharynx was injected. The right side of the palate was paralyzed. There was no respiratory difficulty. The heart, lungs and abdomen were negative. No muscle paralysis or weakness was noted. All reflexes were present and hyperactive. The neck was definitely stiff. The spine was stiff. Both Kernigs were slightly positive. The tache cérébrale was markedly positive.

The temperature was 102.5°, the pulse 160. The respirations were 52.

Examination of the urine was negative. The blood showed a red cell count of 5,800,000. The white cell count was 19,000, 74 per cent polymorphonuclears. On lumbar puncture 10 cubic centimeters of fluid was obtained with an initial pressure of 90. There were 100 cells, 60 of which were lymphocytes. There was a trace of globulin. The total protein was 60 milligrams. The gold curve was 0001112100. No bacteria were seen in the smear.

The boy was given 40 cubic centimeters of human poliomyelitis convalescent serum intravenously. He was given sedatives and was fed by gavage. Lumbar puncture the day after admission showed 84 cells, all lymphocytes, and

a trace of globulin. The initial pressure was 120 millimeters. The child seemed better for forty-eight hours and then began to have great difficulty because of mucus. There was no further development of paralysis. Six days after admission he was rational and cooperative and could expel the mucus from his throat. Respirations were shallow, largely diaphragmatic but the patient could inflate the lungs fully. The temperature was 99.6°, the pulse 112 and the respirations were 20. The white blood cell count was 21,000. He vomited much of the fluid given by gavage. Ten days after admission he became cyanotic due to mucus in his throat which he could not dislodge. The lungs were resonant throughout but the breath sounds were not coming through clearly. He could inflate the lungs feebly when requested to take a deep breath. Use of the respirator was deemed inadvisable. Breathing was accompanied by retraction of the suprasternal hollow. Oxygen was given by nasal catheter. Suction was used to remove mucus from the throat. The child died at 4 o'clock that afternoon.

DIFFERENTIAL DIAGNOSIS

DR. F. DENNETTE ADAMS. The first part of the history in this case naturally suggests trauma and one would have been justified on the second day, when the boy was drowsy, had pain over the eyes and vomited, in assuming that he was developing the symptoms of slow bleeding based on fracture. There are usually however some symptoms due to concussion at the time of the injury in any case experiencing a blow sufficient to cause fracture, and pain in the legs could not be a likely symptom. The fact that he was presumably well again in an other day but again sick two days later excludes injury as the chief cause of symptoms and when by the next day he showed headache, weakness of the legs, difficulty in swallowing and stiffness of the neck it becomes apparent that there is something else seriously wrong. On this evidence alone one would think immediately of acute anterior poliomyelitis, particularly in the summer or fall and in the presence of an epidemic one would have been on the alert on the day after the fall when he first showed pain over the eyes, drowsiness, pain in the legs and vomiting.

When was this boy admitted to the hospital?

DR. TRACY B. MALLORY. In September four years ago.

DR. ADAMS. The time of the year when poliomyelitis is most apt to occur.

The remainder of the history prior to admission is certainly entirely consistent with the bulbar type of poliomyelitis but one should bear in mind the possibility of meningitis—tuberculous rather than epidemic. In any case of presumed palatal paralysis, diphtheria—nasal or pharyngeal—should be thought of, but there

is nothing in this history to suggest it and the Schick test is negative

Physical findings are consistent with infantile paralysis of the bulbar type, although meningitis could give practically an identical picture. The rapid pulse is to be expected in acute poliomyelitis, and the increase in respiratory rate would suggest beginning involvement of the respiratory mechanism. Excluding palatal signs, one could get a somewhat similar clinical picture with severe pneumonia of the central type complicated by meningismus.

The high red cell count was due doubtless to dehydration. The leukocyte count is more consistent with acute poliomyelitis than with the tuberculous meningitis.

The spinal puncture rules out fracture. The pressure of the spinal fluid is low considering the degree of meningeal irritation which seems to be present, but the remainder of the findings are consistent with either poliomyelitis, tuberculous meningitis or the usual types of encephalitis. I suppose that tubercle bacilli were looked for in the smear and not found, but it must be remembered that one negative smear would not exclude tuberculosis. It would also be helpful to know whether sugar was present, as it is usually diminished or absent in tuberculous meningitis or pyogenic infection of the central nervous system.

The course of the disease is quite typical of the progressive case of bulbar poliomyelitis. Whether or not he obtained some relief from the convalescent serum is a matter of conjecture. One wonders why no further doses were given. Possibly it was thought that his apparent improvement after the single dose indicated beginning recovery and that when symptoms recurred it was too late for serum.

I believe the diagnosis in this case is acute anterior poliomyelitis. The history, particularly of mild symptoms with headache and vomiting for a day, then improvement and recrudescence forty-eight hours later, coming on in September, is absolutely typical of this disease. Physical examination, laboratory findings and the course are characteristic of the fatal case of bulbar poliomyelitis with central respiratory failure. Respiratory failure may be the result of involvement of the respiratory center or of the muscles of respiration (diaphragm of intercostals). In most of the latter type (which result from cord involvement) there is usually paralysis of both arms.

Of particular interest is the relationship of the fall to the disease. Did the fall, with possible slight concussion, make more fertile the ground for the infection? Did the fall come as a result of disease already under way or was it purely incidental? We so often find patients blaming falls or other types of trauma for various illnesses that it makes one wonder if previ-

ous injury might not at least contribute by in some way making the patient more susceptible to disease.

A PHYSICIAN: Would we not expect in infantile paralysis to find the polymorphonuclears in the blood being replaced by lymphocytes later on?

DR ADAMS: This change occurs in the spinal fluid. There is no characteristic blood picture in poliomyelitis, the reaction being similar to that encountered in mild respiratory infections.

A PHYSICIAN: The history states there were 100 cells, 60 of which were lymphocytes, in the spinal fluid. At a lumbar puncture there were 84 cells, all lymphocytes.

DR ADAMS: Early in the disease the spinal fluid shows polymorphonuclears predominating, but as the disease progresses these are replaced by lymphocytes.

A PHYSICIAN: Would that pulse rate four days before death be inconsistent with meningitis?

DR ADAMS: No.

A PHYSICIAN: In meningitis is the rate usually slow until the last few days before death?

DR ADAMS: Unless there is marked intracranial pressure the pulse rate in meningitis is usually in proportion to the temperature.

A PHYSICIAN: I wonder why they did not take an x-ray of the skull.

DR ADAMS: The physical examination as well as the spinal fluid findings were doubtless thought to be sufficient to exclude head injury. It would be unwise to take an infectious case of this type through the corridors and expose many patients in the x-ray department and elsewhere, unless it was quite necessary for diagnosis.

CLINICAL DIAGNOSES

Poliomyelitis
Pneumonia?

DR F. DENNETTE ADAMS' DIAGNOSIS

Acute anterior poliomyelitis, bulbar type

ANATOMIO DIAGNOSES

Acute anterior poliomyelitis, bulbar type
Acute bronchitis
Bronchopneumonia
Congenital anomaly—variation in size of kidneys

PATHOLOGIC DISCUSSION

DR MALLORY: The autopsy showed very little in gross. There was no sign of skull fracture. The meninges were congested but not definitely cloudy. The gray matter in parts of the medulla was distinctly red and abnor-

mal looking. In the body we found an acute bronchitis, a very faint trace of bronchopneumonia and some lymphoid hyperplasia which would be diagnostically of no importance but is perfectly consistent with poliomyelitis. Microscopic sections show a slight lymphocytic infiltration of the meninges and a certain amount of ganglion cell degeneration, not very much, but enough to be diagnostic. Dr. Kunk felt that there was no question it was a case of poliomyelitis.

We have had a rather unusual proportion of bulbar poliomyelitis cases in the last four years; in fact the majority that have come to autopsy have shown very little peripheral paralysis. I do not think it represents any change in the character of the disease in this region but rather that this hospital, which was one of the first to put in a respirator, has been advertised in this regard all over New England. Every case with a question of poliomyelitis with a tendency

toward respiratory paralysis is rushed here. The results of the respirator treatment on these cases have not been very brilliant. One of the chief difficulties has been exactly the one shown by this child—paralysis of swallowing results in an inability to keep the throat clear. No matter how careful the nurse is it is almost impossible to remove the secretions in many of these cases. Respiratory infection occurs and the children develop pneumonia and die. We have had a large number of cases with that series of events. Sometimes it does not occur at once. They are put in the respirator and the acute stage of the disease passes but frequently there is never sufficient recovery of the respiratory muscles and the patient is condemned to a respirator life for months before pneumonia mercifully intervenes. A very rare case is carried through respiratory paralysis, recovers adequate strength in the muscles and we are able to point to a dramatic cure.

PATENTS

PATENTS on medicinal and biological agents and on the processes involved in their manufacture may be necessary, but they are not a necessary evil. From what we know of Federal laws concerning inventions and discoveries, it would appear that an inventor or discoverer, if he wishes to uphold his name and reputation and if he is to be free to experiment with or develop his own creation, may be obliged to seek the protection offered by a patent. He may have to do this in order to prevent being estopped by some unscrupulous person who may filch his idea and fraudulently secure a patent of his own. There can, of course, be no objection to gaining such protection. In the case of medicinal agents possessing dangerous possibilities if not properly prepared, and of products that are not controlled by state or federal regulations, a patent is not only desirable but may be necessary. An example is insulin. Here is an organic substance fatal if too weak, because it may fail to relieve the coma of dia-

betes, and equally fatal if too strong, because of the shock it may induce. Insulin, contrary to a general impression, does not fall in the category of biologic products so rigidly supervised by the National Institute of Health of the United Public Health Service. Insulin, and the processes of its manufacture, quite properly required the safeguards afforded by the patent law, not only for the repute of its discoverers but for the safety of diabetics.

Other examples might be quoted, but the one suffices for the present purpose.

It is not a patent *per se* that causes discord, acrimony or other evils. These may lie in the manner in which a particular patent is administered. It is an unwritten law that an inventor or discoverer, supported by public funds whether academic, philanthropic or governmental, should in no way benefit financially from the fruit of his labors. When royalties are applied to research in diseases or subjects not directly connected with the disease to which the taxed remedy directly applies, it may not be pertinent to point out that the royalty is actually paid by an already burdened sufferer, and that it may be unjust to require such a sufferer to contribute to investigations that are of no immediate concern or value to him. This feature of patent administration merits more discussion than has been accorded it.

Then there is the objection—and to us it seems a cogent one—that the holder of a patent may hinder or wholly prevent qualified investigators from studying or improving the product or process covered by the patent. Feeling, as we do, that the experimental sciences should be open to all those whose inclinations, talents and education fit them for serious research without let or hindrance, we entertain no sympathy for such exclusive, mandatory prohibitions.

We do not desire to hold up any patent as an example of personal avarice or of ill-advised or wrongful administration, we do, however, wish to emphasize the fact that the more or less general misconception of our national patent laws, coupled with the misunderstandings, controversies and the ill-feeling they engender, demand the serious, impartial and dispassionate consideration of medical men in general and of the higher councils of our medical and scientific societies in particular.

The Massachusetts Medical Society is, therefore, to be commended for its resolve to request an inquiry into this neglected and threatening question.

RESOLUTION ADOPTED BY THE COUNCIL OF
THE MASSACHUSETTS MEDICAL SOCIETY, JUNE 4, 1935

That the Massachusetts Medical Society is opposed to the existence of the so-called Dick Scarlet Fever patent and the control of this patent by the Scarlet Fever Commission, and, furthermore, that the dele-

gates to the House of Delegates of the American Medical Association be instructed to bring this resolution before the American Medical Association

THE EDUCATION OF THE INTERN

If it be true that the physician should be a student all his life and that his education should be co-terminous with his existence the period of internship should receive more attention from medical educators whether in or out of formal schools. It is for the neophyte a period of especial susceptibility. As an undergraduate he has been seeing patients for some time, yet has had slight responsibility for their care. In the hospital, where perhaps for twenty-four hours a day (on some days) he is continuously dealing with patients, there is opened to him an opportunity for acquiring methods of approach and procedure such as he is likely never to have again. It is a critical period in his development, some what like the breaking in of a colt. If it is not well done, he may be spoiled permanently. Its importance is in some respects greater than the clinical years in the medical school because there is the added personal responsibility for what he does which stamps into him indelibly sometimes with a hot brand the results of his experience. Here it is that he has the opportunity to acquire the habit of scientific method the value of which he may have seen exemplified by his teachers in the medical school.

There are at least two points of view as to the justification for his existence: benefit to the hospital, and benefit to the intern. Outwardly the second good has received the greater emphasis; perhaps the first has, however, been the dominating element in the situation. It is of great benefit to the hospital staff to have the young physicians ready and eager to perform all sorts of ordinary medical tasks for the sake of their own experience. The exploitation of interns has been widespread. Now the intern has become more self-conscious and the possible educational value of the internship is becoming realized. Some medical schools are requiring a year's internship before conferring the doctorate in medicine and some states are requiring a year's internship before admitting to the examination for licensure. Which of these is the wiser procedure time alone will tell, but since the internship should be regarded as part of the education of the physician, the school should have the immediate control in the administration.

The internship has been an important element in changing the atmosphere of the hospitals in the United States. Analogously to the training of the nurse, changing from the exploitation to the education of the nurse, the emphasis in internship is shifting from the use of the intern as a mere means of getting some routine

hospital work done, to the continuation of the education of members of the medical profession.

In all hospitals connected with medical schools the education of students necessarily overflows into some education of interns. But too often it is casual instead of purposeful, systematic and thorough. As the usefulness of internships has been realized and the more urgent competition by hospitals has made it more difficult to secure good candidates, some of the non-teaching hospitals have offered modest honoraria distinctly less than the salary of a well-trained laboratory technician. This merely shifts the emphasis and defers the proper solution.

It has become the duty of every hospital which offers an internship to see to it that the experience is as far as possible for the education of the intern. In this there will be involved some, and occasionally, considerable effort on the part of the medical staff.

In the recent discussion of Internships in Massachusetts Hospitals which appeared in the *Journal** it was suggested that the medical schools, the hospitals, the Massachusetts Medical Society, as well as the interns themselves might form an organization for the consideration and solution of these problems. At present only the interns are unorganized.

As we watch these organizations straining at the leash, so to speak, we wonder in which one eagerness for accomplishment will produce leadership in this movement.

CONFERENCES REGARDING BLINDNESS AND TUBERCULOSIS

Dr. Alix Churchill, associate secretary general of the International Association for Prevention of Blindness and executive secretary of the International Union Against Tuberculosis arrived recently at New York aboard the SS "President Roosevelt" for a series of conferences throughout the United States regarding policies and procedures in

the world wide fight against blindness and tuberculosis. She is here as the guest of the National Society for the Prevention of Blindness and the National Tuberculosis Association.

The International Association for Prevention of Blindness whose headquarters are in Paris is a clearing house for information on scientific and educational activities for the conservation of vision in thirty-six countries including the United States.

Americans were largely responsible for the establishment of the Association at a conference at The Hague in 1929. The next annual meeting will be in Paris in the spring of 1936.

The International Union Against Tuberculosis is a conference body composed of forty-four nations, including the United States, whose headquarters are also in Paris. Its objective is to promote the world-wide campaign against tuberculosis by furnishing a clearing house and forum for the scientific and administrative problems involved. Biennial meetings are held in the member countries. The next international conference will be held in Lisbon, Portugal, in September, 1936.

In addition to conferences with the executives of health agencies in New York City and Washington, D. C., Dr. Churchill will observe the activities for prevention of blindness and tuberculosis in the following cities which she is scheduled to visit: Buffalo, Chicago, Denver, St. Louis, Philadelphia, Washington, Baltimore, Boston and Toronto.

The blind population of the world is estimated to be about five or six millions, according to Dr. Churchill. Most of the causes of blindness are preventable, she said. There is a steadily growing interest among European educators in the use of "sight-saving classes" as a means of educating children with seriously defective vision, and one of these special classes was started in Paris last year. The movement has grown more rapidly in America than anywhere in the world; there are now 462 sight-saving classes in 144 communities throughout the United States.

RECENT DEATHS

LEONARD—WILLIAM E. LEONARD, M.D., a retired physician of Hadley, Massachusetts, died August 28 while visiting with relatives in Minneapolis. Dr. Leonard was born in 1855 in Minneapolis and received his M.D. degree from the Hahnemann Medical College and Hospital of Philadelphia. He had practiced in Minneapolis for more than fifty years and retired to make his home in Hadley with his daughter in 1929.

He was active in town affairs in Hadley and a member of several local organizations.

BUCKLEY—CORNELIUS J. BUCKLEY, M.D., for several years a member of the Staff of the United States Veterans' Hospital and also formerly of Springfield, Massachusetts, died at the home of his brother, in Pittsfield, Massachusetts, September 1, 1935.

Dr. Buckley was born in Stockbridge, March 8, 1876, the son of Patrick J. and Johanna (Broderick) Buckley. He graduated from the Albany Medical College and served several years at the Bedford Hospital.

He is survived by his widow, Mrs. Cora B. (Van Ness) Buckley, and a brother, Richard Buckley.

BIXBY—JOSIAH P. BIXBY, M.D., of 20 West Street, North Woburn, Massachusetts, died September 2, 1935. He was born at Norridgewock, Maine, in 1854 and, after preliminary education at Andover, studied medicine at the Bowdoin Medical School, graduating in 1876. He settled in Woburn in 1884 and, after having been a member of the Massachusetts Medical Society for many years, retired in 1923.

Dr. Bixby is survived by two sons, William P. Bixby of Woburn, Frederick Bixby of Tampa, Florida, and a daughter, Mrs. Elizabeth Siegfried of Glen Ridge, New Jersey.

NOTICE

ANNOUNCEMENT

MOSES J. KONIKOW, M.D., has opened an office at 636 Beacon Street, Boston. Telephone Kenmore 9600.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, SEPTEMBER 9, 1935

Wednesday, September 11—
112 M. Clinico-Pathological Conference Children's Hospital

Saturday, September 14—
10-12 Staff rounds at the Peter Bent Brigham Hospital

*Open to the medical profession
†Open to Fellows of the Massachusetts Medical Society

September 17, 18, 19—Eleventh Clinical Congress of the Connecticut State Medical Society. For details address Dr. Creighton Barker, 129 Whitney Avenue, New Haven, Conn.

September 30—October 12—International Medical Post-Graduate Courses in Berlin. For further information apply to the Geschäftsstelle der Berliner Akademie für ärztliche Fortbildung, Robert Koch-Platz 7 (Kaiserin Friedrich Haus), Berlin N. W. 7.

October 6-20—Seventh Annual Training Course for Medical Residents at the Mayo Clinic. See page 441, issue of August 29.

October 7-10—American Public Health Association will meet in Milwaukee, Wisconsin. For information address the American Public Health Association, 50 West 50th Street, New York City.

October 21—November 2—1935 Graduate Fortnight of the New York Academy of Medicine. See page 898, issue of May 9.

October 28—November 1—The Twenty-Fifth Clinical Congress of the American College of Surgeons. See page 1065, issue of May 30.

BOOK REVIEWS

Clinical Management of Syphilis. Alvin Russell Harnes. 71 pp. New York: The Macmillan Company. \$1.50.

While the book is attractive in appearance, and its purpose—"to offer courses of therapy for the management of syphilis at whatever stage it may present itself to the general practitioner"—praiseworthy, the contents fall far short of one's expectations. The statement on the jacket that "This book is unique in that the author has outlined the treatment of the various forms of syphilis giving the day by day and week by week tables of medication for a period of three years" disregards the

fact that J F Moore in his *The Modern Treatment of Syphilis* published in 1933 and J H Stokes in the second edition of his *Modern Clinical Syphilology* in 1934 did just this

The book not only fails to present anything new but it fails to take note of much of the advance in the subject of the last five years as shown in the fact that twenty per cent of the chapter on Syphilis of the Central Nervous System is devoted to the once-valuable Swift-Ellis technic. While mercury still holds its place in treatment few specialists are using mercury injections with their excessive painfulness and danger when they now have a safer and more active weapon in the form of bismuth, yet this author recommends bichloride of mercury injections in early syphilis a stage of the disease when most syphilologists feel that time is too precious to waste on so ineffective a drug. Every one of course insists on the treatment of the pregnant woman during her first pregnancy in which syphilis is discovered, but instead of recommending subsequent treatment as far as possible in the intervals of her childbearing the author recommends treatment during each and every pregnancy regardless of blood tests or the amount of previous treatment.

The directions for personal hygiene contain the amazing statement that bath-tub and toilet seat must be washed with an antiseptic. The reviewer is not aware that the bath-tub has ever been blamed for a case of syphilis and it is well known that toilet seat infections are so rare as to amount only to alibi. Insistence on delaying marriage "until eighteen months after the blood and spinal fluid serology is (are) permanently negative" takes us back to the days of mercury inasmuch as it can never be known when a person reaches the point of permanent negativity such a requirement is equivalent to refusing the privilege throughout life. Modern thought is strongly tending toward what Stokes calls "protected marriage" rather early and under medical supervision. In the treatment of cardiovascular syphilis we read that "treatment of these patients must of necessity be carried on with extreme measures of precaution" and on the next page we see the suggested course of treatment which is hardly cautious and lacks little of being classifiable as intensive. In the chapter on Congenital Syphilis we learn that since the mother is receiving treatment, the child must be given mother's milk from some other source or placed on whole cow's milk formula.

The book is replete with careless spellings and abbreviations: nitrold for nitritol, Tr pallidum and Tr pallida used interchangeably for T pallidum, Bloch for (Iwan) Bloch and many others. Of the fifteen references in the bibliography about one-half are to good but minor articles by the able leaders of the author's city. It is to be hoped that failure to mention J E Moore and P C Jeans and J V Cooke does not mean that their writings are not familiar. The index is well done.

Diagnosis and Treatment of Skin Diseases Including the care of the normal skin. Jacob Hyams Swartz and Margaret Gilson Reilly. 316 pp. New York: The Macmillan Company. \$3.50.

This book is essentially a practical one in the treatment of skin diseases. The directions for the application of therapeutic measures are detailed and explicit, and they are combined with sufficient data concerning a given disease for the nurse or medical student.

The chapters on the care of the baby's skin and on the care of the abnormal skin together with the chapter on syphilis should be extremely valuable for every nurse and medical student. The curriculum outlined for nurses is an ambitious one fully capable of being carried out in a large hospital, and it should provide a valuable experience in this field for nurses.

The classification of diseases by regions entails numerous references to other chapters but is convenient for teaching purposes. The photographs are excellent. There are numerous tables of differential diagnosis as well as many lists of articles needed in a specific procedure. The formulary contains prescriptions tested and found worthy during many years in a large and varied skin clinic.

This book should prove to be of extreme usefulness to nurses and medical students and there are many valuable suggestions for the general practitioner in carrying out the treatment of common skin diseases.

Hertzer's Monographs on Surgical Pathology Surgical Pathology of the Peritoneum. Arthur E. Hertzer. 304 pp. Philadelphia: Montreal and London: J B Lippincott Co.

This interesting monograph is much more than an article on the pathology of the peritoneum. It covers also anatomy, physiology and surgery and contains much material on diseases and conditions that only affect the peritoneum in a secondary manner. Parts of it are very good, other parts only fair and there are some surprising omissions. On the whole it should be read and studied by all those doing abdominal surgery especially if their results are not what they should be. It is never dull.

Samples of good paragraphs follow.

"Tympany is purposive in some cases. It aids in localizing infections by quarantining the area and it slows absorption of the peritoneal exudates by increasing the intra-abdominal pressure. Therefore distention per se is not always an evil and as a matter of fact the measures to combat it are often more injurious to the patient than the condition itself.

"Death from intestinal paralysis as I used to see it in my pathology days was something like this. A day or so after a slow operation punctuated by profuse conversation and zealous pawing of guts the patient became distended. At once this distention was persistently and vigorously combated by

enemas and other means until the patient foolishly c. eu If the term 'paralysis' is applicable to such cases it must denote the attempts at stimulating peristalsis at a time when the intestines are protecting an irritated area and refuse to be stimulated into action. An interesting observation from the pathologist's point of view is that some surgeons are constantly plagued by this disaster while others never experience it."

One example of what is, in the reviewer's mind, poor advice is that gauze packs are always advised for drains, rather than rubber tubes or cigarettes. It is only fair to state, however, that the author is insistent on the proper placing of drains so that I am sure that gauze packs used by him are much safer than other drains used by certain others.

A surprising omission is the leaving out of all consideration of that numerous and very troublesome group of cases of combined ileus and obstruction seen following operations for appendicitis with general peritonitis.

Textbook of Attendant Nursing Katharine Shepard and Charles H. Lawrence 433 pp New York The Macmillan Company \$3.00

The names of the authors give assurance of good judgment in the preparation of this book. If any further commendation is sought by readers, the list of contributors and reviewers will be an added endorsement.

In the early chapters, a description of the elementary structure and gross anatomy of the human body, together with brief references to the diseases to which each organ is subject, will prepare those who are responsible for the care of illness and maintenance of health to give adequate and intelligent service.

The sections given to household problems including the selections and preparation of foods are followed by dietary rules for invalids and children all of which are of greater importance than is generally recognized.

The second half of the volume is especially directed to nursing fields and, if carefully studied, will qualify the nurse for practically all of her duties.

This very excellent book will interest the doctor, medical student, hospital administrator, and all ambitious nurses. It is a useful book of reference for the family library.

Anaesthesia and Analgesia in Labour Katharine G. Lloyd Williams 96 pp Baltimore William Wood & Company \$2.00

This little book describes in detail the use of anesthetics and analgesics in England. The methods that the author suggests have not appealed to American obstetricians, and it is not a book that can be of much service in this country.

Female Sex Perversion The sexually aberrated woman as she is Maurice Chideckel 352 pp New York Eugenics Publishing Company \$6.00

Dr Chideckel's book on female sex perversion is a semipopular presentation of the subject. The author's experience with such cases seems to have been fairly extensive, as he quotes numerous examples well within his practice. These illustrations, together with other cases abstracted from the literature, serve to present to the reader, in concrete form, examples of the major forms of sex perversions in women.

In the main, the book consists of descriptions of the various types of perversion. The author has evidently read widely in the literature dealing with this subject, and accepts the teachings of Freud as regards the causation of these abnormalities. Some of his statements appear rather overemphatic, as for example "Masturbation, therefore, must be regarded as an important factor in the causation of mental diseases." He states definitely that this effect is brought about not by the practice itself, but by the fear of insanity which is aroused in the woman by what she reads or hears about the results of masturbation. Even so, his statement appears rather sensational.

Another startling pronouncement is that "Nudism is exhibitionism. The nudist is a sexual pervert." This opinion would seem somewhat extreme. Dr Chideckel's reference to sodium bicarbonate as an "alkaloid" (p. 275) is hardly consistent with the nomenclature of modern chemistry.

Taken as a whole, the book does not leave one with the feeling that it is a really scientific presentation of the subject. It is an attenuated echo of the more profound works of such authors as Havelock Ellis, Krafft-Ebing, Moll and Freud, served with a dash of sensationalism to whet the appetite of the superficial reader.

Modern Motherhood A book of information on complete maternity care Prenatal—Delivery—Aftercare Claude E. Heaton 271 pp New York Farrar & Rinehart, Inc. \$2.00

Modern Motherhood is a book of some 270 pages. It contains much that is of value to the mother, but it also has a great deal of material that is totally unnecessary in any book that is written primarily for the instruction of mothers. The author states that a special diet is unnecessary and then goes into a twenty-page discussion of diet, with tables of calories and a consideration of the vitamins. His discussion of anesthesia and analgesia is entirely too detailed. The book contains a bibliography of articles and books that would be of no help to mothers in going through a pregnancy.

If the book were cut to half the size of the present volume it would be most welcome and readable, and could well be given to mothers for their use. In its present form, however, it is not acceptable for such a purpose.

The Massachusetts Medical Society

SECTION OF RADIOLOGY AND PHYSIOTHERAPY

Ball Room Assembly, Hotel Statler, Boston, Monday, June 3, 1935, 2 30 P.M.

PRESIDING

Franklin P. Lowry, Newton, Chairman
Philip H. Cook, Worcester, Secretary

CHAIRMAN LOWRY: The Section will please come to order. Is there any business to be transacted at this time?

Your committee has worked for nearly a year on subjects that we thought would be interesting for both the roentgenologists and the physical therapists. We have three interesting papers this afternoon.

We are sorry that Dr. Vogt, about a week ago, was called to his home in Iowa because of sickness of his mother and has been unable to return. Dr. Green could not conduct the discussion because it was necessary that Dr. Vogt start the papers with x-ray slides which Dr. Green was to discuss later. With your consent I am going to ask the secretary to write Dr. Vogt and Dr. Green, telling them of our sorrow in the sickness of his family and that we are much disappointed in not hearing the papers. Does that meet with your approval?

(The meeting so indicated.)

CHAIRMAN LOWRY: In the field of physical therapy there are a great many new types of apparatus being brought out almost continuously. The Council on Physical Therapy has tried to select the good ones and to eliminate the bad ones and in some instances has been successful. One of these pieces of apparatus which is before the general practitioner at the present time is the so-called short wave high frequency machine or "short wave diathermy" or radiotherm. In order that we may find out more about it and use it more intelligently, we have asked a physicist to come and tell us what is inside and a clinician to tell us what happens outside the box as we use this particular machine.

We are very fortunate in having Dr. Chaffee, professor of physics at Harvard University, who has gladly consented to speak to us on the physics of high frequency machines. His particular subject is "The Physics of the High Frequency Currents as Used in Medicine"—and there are three of them—"Diathermy, Radiotherm and the Electric Knife." Dr. Chaffee!

THE PHYSICS OF HIGH FREQUENCY CURRENTS AS USED IN MEDICINE—DIATHERMY, RADIOTHERMY, AND THE ELECTRIC KNIFE*

BY E. L. CHAFFEE, PH.D.†

The modern medical man makes use of a great many agencies and devices which have come directly from the physicist's laboratory. Such agencies as x-rays, radium, ultraviolet light and devices such as the electrocardiograph have been invaluable in the medical world. An understanding of the scientific principles underlying these physical agencies is highly desirable as a guide in the medical applications, as a guard against wrong and dangerous usages, and as a defense against extravagant and unwarranted claims. Often reticence in accepting new and useful devices is fostered by ignorance, while on the other hand ignorance often leads to abuse and tragic misuse of valuable agencies.

During the last few years there has been a rapidly increasing use of high frequency currents of electricity in diathermy and in surgery.

One hears of short waves of damped and undamped waves of conduction and capacity currents, and a host of other scientific terms. The object of this talk is to explain the meaning of some of these terms and briefly to explain how the currents are generated and applied.

First, why are high frequency currents used in preference to low frequency currents? When a current which alternates in direction a small number of times per second, say sixty or one hundred times per second, is passed through living tissue, the electrolytic ions move to and fro with the alternations. As a consequence, polarization of the cells, electrolysis, nerve stimulation and muscular contraction take place, and a very small amount of heat is produced. If the frequency is increased into the tens of thousands of alternations per second, the ions have less time to move and all effects except heat rapidly disappear. With frequencies of hundreds of thousands of alternations per sec-

*Read at the Annual Meeting of the Massachusetts Medical Society, Section of Radiology and Physiotherapy, June 3, 1935.
†Chaffee, E. L.—Gordon McKay Professor of Physics and Communication Engineering, Harvard University. For record and address of author see "This Week's Issue," page 544.

and the only effect remaining is heat and the absence of nerve stimulation and destructive electrolysis permits large currents to be passed without harm through the body with the consequent increase in the heating effect.

I feel quite sure of my position in stating that no specific effect of any particular frequency has been proved to exist, nor is there any reason to expect any specific effect because the highest frequencies used are far too low to elicit any specific molecular activities. If this statement stands the test of time, the only effect used in diathermy is the heating effect.

The rate of production of heat at any point in the body depends upon the square of the current density and the specific resistance of the tissue. The so-called "skin effect", which means the tendency of a high-frequency current to travel mostly in the surface of a conductor, is negligible when the body is the conductor. It is fairly well established, however, that the surface of the body is more intensely heated than the interior, but this uneven heating can only be due to the greater resistance of the subcutaneous tissue and to the higher current density at the electrodes, especially when small electrodes are used. The circulation of the blood is a powerful agency toward equalizing the temperature throughout the body.

Some diathermy machines generate currents of the order of a million alternations per second, while the so-called "short wave" machines apply currents having frequencies from about ten to one hundred million alternations per second. The term radiotherapy has been suggested to imply the use of very high-frequency currents. All machines produce heat in the body, the principal difference between the use of the high and the ultra-high-frequency machine lies in the mode of causing the currents to pass through the body. This will be explained later.

What is the difference between damped and undamped currents and how are these two types of currents generated? Everyone who has taken a course in elementary physics is taught that when a condenser or Leyden jar discharges through a spark gap and a few turns of wire, the current surges back and forth like the oscillations of a pendulum which has been pulled aside and released. The oscillations die down, that is, they are damped. The condenser may be repeatedly charged and allowed to discharge, producing a series of damped trains of oscillations. This was the method of generating the oscillations used in early radio telegraphy, and it was natural that the same artifice should be used in the first "spark gap" diathermy machines. The currents produced by these machines consist of separated groups of oscillations, each group consisting of from ten to one hundred oscillations of diminishing amplitude.

Generally there are relatively very long intervals of time between trains or groups when no current flows.

The invention of the thermionic vacuum tube provided means for exciting continuous oscillations in a circuit in much the same way as a clock mechanism maintains a pendulum in continuous oscillation by giving it a gentle push each swing. The vacuum tube rapidly supplanted the "spark gap" radio transmitter, and so the vacuum-tube diathermy machine has practically made obsolete the "spark gap" diathermy machine.

Let us contrast the two types of current. Both types of current, the damped and the undamped, produce heat, but for the same amount of heat the damped current must rise to very much higher instantaneous values because of the long pauses when no current flows. As a consequence, for the same degree of heat, the damped currents produce much higher instantaneous voltages and these higher voltages favor the production of sparks and burns. The undamped current, on the other hand, is smooth, steady and continuous, and has the minimum tendency toward sparking.

A few other points are relevant concerning the generators of damped and undamped currents. Every diathermy machine consists essentially of an oscillatory circuit comprising a condenser and an inductance, which is caused to oscillate either by repeatedly charging the condenser and allowing it to discharge through spark gaps, or by exciting the circuit by vacuum tubes. The size of the condenser and inductance determines the frequency. Power is drawn off from this storage circuit by various means, either by capacitive or inductive connection. The spark gaps are troublesome things requiring cleaning, and they are irregular in action and require frequent adjustment. On the other hand, the vacuum-tube generator works with the steadiness and regularity of a good watch and the currents it generates are steady and easily adjusted and controlled. The early "spark gap" radio transmitters caused a great deal of interference in radio reception and are hence not tolerated today except for sending SOS signals. So, too, the spark-gap diathermy machine produces a great deal of radio interference, and is hence a nuisance to radio enthusiasts.

There are several ways of causing the high frequency currents to pass through the patient. At the lower frequencies of a million cycles, the most effective way of applying the heating currents is by direct connection of the patient to the machine. Moistened pads or metallic electrodes are fixed to two places on the patient's body and these electrodes are connected by wires to the machine. The high-frequency currents pass through the patient as a part of an electric circuit. Because the current is con-

ducted to the patient by wires, the current is often called a *conduction current*.

When the frequency is very high, currents can be caused to surge in the body without actual contact. To explain this, imagine a conducting body situated between two metal plates and separated from them by air spaces. If the plates are charged, one positively and the other negatively, induced charges appear on the surfaces of the body opposite the two plates. These induced charges arise from a momentary flow of electricity within the body. If now, the charges on the plates are reversed the induced charges on the body reverse and this reversal is brought about by another surge of electricity through the body in the opposite direction. If the plates are alternately charged first one way and then the other, electricity surges back and forth in the body to supply the induced charges on the surface of the body. The greater the number of reversals per second the greater the number of surges of electricity through the interior of the body and the greater the rate of production of heat. It is evident that currents in the body produced in this way increase with the frequency and only at the frequencies of from ten to one hundred million alternations per second are these currents sufficiently intense to produce a practical amount of heat. The currents which surge to the plates from the machine and those which surge in the body are sometimes called *capacity currents* but it is to be emphasized that capacity and conduction currents are qualitatively identical.

There are undoubtedly certain advantages in the capacity method of connection between the patient and the machine. The metallic electrodes are generally imbedded in rubber or some other insulating substance so that there is no direct connection from the machine to the patient. This considerably diminishes the danger of any low frequency currents passing through the body incident to any accidental breakdown in the machine. Furthermore, the insulation diminishes the danger from burns due to sparks and arcs.

A third method of applying high frequency currents is that suggested by Dr. W. R. Whitney of the General Electric Company. A heavily insulated wire carrying high frequency currents is wound several times around the portion of the body to be heated. Currents are induced in the tissues through the action of the magnetic field instead of through the electrostatic effect. The induced currents circulate in paths which follow more or less closely the contours of the coil, and heat is conveyed into deeper regions by conduction and by the blood. Here again the body is not in direct contact with the machine and danger from burns due to arcs and sparks is considerably diminished.

Claims have been made that differential heating can be obtained, especially at ultra high

frequencies, so that one organ or part can be heated to a greater degree than the surroundings. Some of these claims are based on measurements of temperature obtained by inserting thermocouples into various parts. One should look with suspicion upon any temperature measurements made with thermocouples or with any temperature measuring device which is a conductor of electricity, because such thermometers are heated by high frequency currents produced in them during the operation of the machine. Furthermore, the distribution of current in the tissue may be changed by their presence.

McLennan and Burton* have shown experimentally and mathematically that corresponding to each frequency there is a particular specific resistance of the tissue which evokes the greatest heat production. It should be noted, however, that this does not mean that corresponding to each specific resistance there is a frequency which evokes the greatest heating. With this scientific fact before us, it is impossible to say that differential heating is impossible, although considering the temperature equalizing effect of heat conductivity and blood flow, it seems very doubtful that differential heating can be accomplished and controlled to any practical extent.

The action of high frequency currents in surgical cutting and in coagulation, desiccation, etc., again depends upon the heating effect of the currents. A small electrode gives a high current density at the electrode with a consequent rapid production of heat and a high temperature. If the temperature is sufficiently high, coagulation results and if still higher destruction and carbonization take place. If the electrode is not in close contact with the tissue an arc or spark bridges the gap and high temperatures are produced in very localized areas, and the cells are disrupted.

When the current density at the electrode is increased beyond that necessary for coagulation, cutting takes place. Usually the electrode is smaller than for coagulation, to increase the current density. It may be a needle, a wire, or a thin, narrow blade. A good incision shows very little coagulation and no carbonization, which indicates that some effect causes the cutting other than the high temperature produced by the passage of the current through the tissue. McLennan† states that there is a minute arc between the electrode and the tissue when a satisfactory incision is made. This seems to be the most plausible explanation of the cutting effect. A thin film of gas or vapor between the electrode and tissue maintained in an ionized

*McLennan, J. C., and Burton, A. C. The heating of electrolytes in high frequency fields. *Canad. J. Research.* 3: 234 1936.

†McLennan, A. J.: Davis electro-surgical current generator, some underlying principles and results. *Arch. Surg.* 18: 1863 1929.
Characteristics of adequate electro-surgical current. *Am. J. Surg.* 18: 417 1929.

state by the current would account for the relatively high voltage of about 200 to 250 between the electrode and tissue for a good incision. The rapidity with which a cutting electrode advances and the absence of coagulation except in the surface of the cut, are consistent with the idea of an extremely intense and localized heat. The blade or electrode remains clean as if it never came in contact with the tissue. The film of ionized vapor probably separates the electrode from the tissue so long as it is maintained but if the power supply is too low the film is dissipated, the tissue sticks to the electrode, and cutting ceases. Damped currents have not been so satisfactory for cutting as the undamped currents and can be used only by making the number of trains of oscillations per second very large by shortening the spark gap. It is probable that periods of no current flow allow the ionization to dispel unless the inactive periods are very short, whereas the continuous undamped currents more effectively maintain the ionized film.

Barring any specific biological effects, either in diathermy or in electrosurgery, about the only factors influencing the choice of frequency are the modes of application, whether by direct contact or through capacity electrodes. The ultra-high frequencies are less satisfactory for electrosurgery because of the large currents which pass through small capacitances, such as that formed by the surgeon's hand grasping the insulated cutting electrode. The ultra-high and high frequencies are advantageous in diathermy where application through capacity electrodes is preferable. The increasing number of uses of this new agency has considerable influence in determining the choice of frequency, and it is probably best to leave this point open for the physician and for future developments to decide.

DISCUSSION

CHAIRMAN LOWRY There is a doctor in New York who is giving a good deal of his time to research, who has done much to rationalize physical therapy. That is Dr. Bierman, and it gives me great pleasure to welcome him here as a fellow member of the Academy of Physical Medicine, to speak to us this afternoon. Dr. William Bierman of New York City.

DR. WILLIAM BIERMAN *Mr. Chairman and Members of the Massachusetts Medical Society and Guests*—Permit me first to make some little changes in the title of the paper as it has been assigned to me. I shall not discuss the subject of fever or temperature elevation of the entire body as created

by the short wave current or by any other mechanism. I shall limit myself to the question of the therapeutic use of short wave currents and I want to take the liberty of doing that, because I realize that at the moment there is a very strong controversy as to the relative merits of the short wave current and the other method of convulsive heating which we have used for a period of years, diathermy.

Now, as to the term "short wave radiation", the word "radiation", as Professor Chaffee has told you, is a misnomer. We are not dealing with radiation frequencies, thinking of the word as we apply it to x-rays, or to radium, or radiations from luminous or ultraviolet sources. We are dealing with actual current flow, and so the use of the word "radiation" should be deleted from the title. I have done so on the title of the paper which I have with me here this afternoon.

That leaves us just two other words, "short wave". We feel with Professor Chaffee that the terminology is very labored, and inadequate. In defining the method which we use, we should possibly refer to the frequency of the current. I have thought that we might refer to the application in megacycles, because it makes it a bit more awkward to say "one hundred million cycles". It is much easier to refer to the terminology of the physicist or engineer, and refer to the subject in megacycles. It may well be that our clinical evaluations of the results through the years and in different parts of this country and abroad, would be much better if we had definite knowledge of the exact frequencies used by one man in contrasting his results with the frequency of the currents used by another man.

I think now that we have torn the title to pieces, and agreed not to use any part of it, except as to present usage, the title of the paper before me is "The Therapeutic Use of Short Wave Currents." My paper is a relatively long one, because I have asked the physicist with whom I work, Mr. Schwarzschild of the Beth Israel Hospital, to write that part which deals with the physics. I knew Professor Chaffee would discuss that subject with you, but I as a physician know that it becomes very difficult for a physician to deal with the subject of the physicists, conductive currents, capacity currents, or as we have referred to it here, the displacement currents. Just what is the difference? I can attempt to explain it to you, but in the presence of an authority far greater than I, I would defer the matter to Professor Chaffee, and so you are saved from my perusal of the first eight pages of my discussion, although I feel justified in including them in the paper as it may be printed, so that those of you who may desire may read our explanation of the difference between the currents produced by machines whose frequencies are much smaller than those produced by so-called short wave apparatus. I will encroach somewhat on Professor Chaffee's field, and show determinations we have made from studies of the phantom, studies made on animal tissue, both dead and living, to give you some little understanding of the somewhat different action of the heating of currents of relatively low and relatively high frequencies, and if we can have our first slide we will begin.

(Dr. Bierman then read the paper on "The Therapeutic Use of Short Wave Currents", illustrating his discussion with lantern slides.)

THE THERAPEUTIC USE OF SHORT WAVE CURRENTS*

BY WILLIAM BIERMAN, M.D.,† AND MYRON SCHWARZSCHILD, M.A. †

ONE of the most important properties of the electric current is its ability to heat substances through which it passes. This property cannot be used indiscriminately for heating human tissue because, unfortunately, there are basically chemical effects accompanying the passage of this current through tissue. In order to avoid these chemical effects, it is necessary to use electric currents the direction of which changes rapidly, the so-called alternating currents. There are two important ways of specifying the number of alternations: a second the first, and the simplest, is merely to specify that number. This is done in ordinary technical applications of electricity where we speak of sixty cycle current, for example, meaning that the number of alternations a second is sixty. Where the number of alternations is very high, in order to avoid the use of very high numbers it has been customary to refer to a quantity known as the *wave length*. The vibrations of the electric current travel with the speed of light, three hundred million meters a second so that if the frequency of alternations is one million, for example, the wave length (that is, the distance between successive peaks of current) would be three hundred million divided by one million, or 300 meters. This is in the range of frequency of ordinary diathermy. A short wave apparatus which produces a wave length of ten meters is producing an electric current whose frequency of alternation is three hundred million divided by ten, or thirty million alternations a second.

All heating by electric currents is basically of the same nature. At any point in a substance, the heat generated depends upon the electric field strength at that point and the conductive current at that point and, in fact, it is proportional to the product of these two quantities, and aside from magnetic effects involves no others. The problem of determining the distribution of heat in a mass of tissue when it is subjected to the action of diathermy or of short wave resolves itself, then, into the problem of determining the electric field strength and the conductive current density at every point in the mass.

These two quantities vary in magnitude from point to point in the medium, and their distribution depends upon the geometric arrangement of the electrodes, the size and shape of the medium,

and the distribution of electric constants in the different parts of the medium.

It is necessary at this point to distinguish between *conductive* current and *total* current. In a varying electric field such as is produced either with a diathermy machine or a short wave machine, where the field changes its direction many times a second, the current at any point does not necessarily follow the electric field, that is to say, when the electric field is a maximum in one direction, the current may not be at its maximum value in that direction, and when the field intensity is reduced to zero preparatory to going in the opposite direction the electric current may not simultaneously be zero, but may have some value in one or the other direction. In such a case, we speak of a difference in phase between the current and the field strength, or voltage. While both are varying in a sinusoidal manner, there is a time difference between the attainment of maximum value, the current attaining its maximum value earlier or later than the field intensity. A current varying in this manner *out of phase* with the field intensity which produces it may be considered as made up of two components: one a so-called *displacement* current, which is completely out of phase with the field intensity, that is to say, it attains its maximum at the instant when the field intensity is zero and runs through the zero point at an instant when the field intensity is a maximum. The other component we have called the *conductive* current. It is entirely *in phase* with the field intensity, attaining its maximum at the same instant as the field intensity maximum and passing through its zero value at the same instant as the field intensity passes through its zero value. The actual current at any point is, of course, the total, that is, the sum of these two currents, and its phase is shifted with respect to field intensity, but for the purpose of studying the power dissipation, that is, the conversion of electric energy into heat, it is necessary to separate the current into these two components, displacement and conductive currents, and the heat at any point is independent of the displacement current but is proportional to the product of the conductive current and the field intensity.

The value of the conductive current and the field intensity at any point in the medium, of course, depends not only upon the electric constants of the point in question, but also upon the electric constants of other parts of the medium. The study of the interaction of one part of a medium upon another is the most difficult part of the problem.

In diathermy, where the frequency of alternations is relatively low as compared with the

†Bierman, William—Attending Physiotherapist, Mt. Sinai Hospital, New York. †Schwarzschild, Myron—Physicist, Beth Israel Hospital, New York. For records and addresses of authors see "This Week's Issue"—page 644.

short wave, we may for practical purposes assume that the current at any point is wholly conductive. Under these conditions, the current distributed through the medium and the distribution of electric field through the medium depends upon a well-known constant of matter, *conductivity*. Such a simple idea as the current takes the path of least resistance is here applicable and we can predict with some assurance the direction and magnitude of the current at various points by making use of this simple concept. Since the current here is entirely conductive, that is, completely in phase with the electric field, we may conclude that the heat developed at any point, being proportional to the current times the field intensity, is in fact proportional to the square of the current, and the proportionality factor involves only the conductivity.

When the frequency is increased and we come into the range of tens of millions of alternations a second, the problem becomes considerably more involved. Here we can no longer neglect the displacement current, that is, the component of the current which is out of phase with the electric field. At infinitely high frequencies the current is all displacement current and no heat can be developed. At intermediate frequencies, that is in the range of so-called short waves, we must endeavor to determine the distribution of conductive currents and of field strengths. To form any conception of the distribution of conductive current it becomes necessary to determine the distribution of total current, that is, to determine the displacement current as well. The displacement current depends for its distribution upon the electric characteristics of the medium known as the dielectric constant. The dielectric constant has a meaning for the displacement current essentially similar to the meaning of conductivity for the conductive current. The conductivity is a measure of the conductive current which would be produced in a substance by a unit of electric field strength. The dielectric constant is, in a similar way, a measure of the displacement current which would be produced in a medium by a unit of field strength. Here again we must remember that the dielectric constant at a single point is not sufficient to tell us the displacement current, but account must be taken of the interaction of other parts of the medium. This point is the stumbling block for any simple explanation of the distribution of heat.

The interaction of other parts of the medium upon the point in question is a matter fraught with great mathematical difficulty and has only been completely solved in very simple cases. Certain simple types of distributions will be considered for the purpose of showing how this interaction functions and wherein the difference

lies between the low frequency diathermy and the high frequency short waves.

Suppose we have a pair of electrodes placed on either side of a mass of fatty tissue and we arrange matters so that a certain fixed total current flows through the circuit. Fatty tissue has a low conductivity but a reasonably high dielectric constant. If the frequency is very low, all current measured by the meter is conductive current and since the conductivity of the material is low, the electric field strength necessary to drive this current through the material must be very high. Hence the product of electric field strength and current is high. Now if the frequency is increased, keeping the current the same, some of the current no longer remains conductive but becomes displacement current, so that for the same total current only a portion of it is in phase with the electric field produced. Since the conductive current and the field intensity are proportional, the decrease in conductive current must be accompanied by a decrease in field intensity. Hence both factors, the electric field strength and the conductive current, are lower than they were in the low frequency case so that the total heat developed is reduced. It follows thus as a result of this consideration that per unit of current, the lower frequency is more effective in heating than the high frequency.

It is of course not to be concluded that the high frequency cannot be used to produce heat in such material because it is easily possible to raise the current to a point where in the high frequency case the same amount of heat would be developed as in the low frequency case. But for current of the same magnitude, the low frequency is the more efficient heating arrangement.

Now suppose that between these two plates instead of a mass of fatty tissue we have two layers, one of fatty and one of vascular material. In the fatty substance the dielectric constant is somewhat lower than that in the vascular tissue, while the conductivity of the vascular tissue is much higher than the conductivity of the fatty tissue. Let us repeat our imaginary experiment and pass a current of definite magnitude between these plates. At low frequency the dielectric constant plays no rôle because there is no displacement current and the field intensity in the low conductivity fat must be much higher than the field intensity in the high conductivity vascular tissue. Since the current is the same in both and is all conductive, the fatty tissue becomes hotter than the vascular tissue. Now if the frequency is increased to a sufficiently high value so that a considerable part of the current is displacement current, the heat distribution changes completely. In the fatty layer with its low conductivity, practically all the current may be displacement current while in the vascular tissue, since

the conductivity is high, a considerable portion of the current remains as conductive current. The total current is the same in both parts but now the conductive current which is the important one for the calculation of heat conversion is higher in the vascular tissue than it is in the fatty tissue. The field strengths in the two types of tissue of course, will depend upon the conductive current, and since this is now higher in the vascular tissue than in the fatty tissue, the heat generated will be higher in the vascular tissue. By a suitable selection of frequency it is possible to attain a frequency at which the heating is the same in both. This will be the frequency at which the field strength in the fatty tissue is greater than in the vascular tissue by the same proportion as the conductive current is greater in the vascular tissue than in the fatty tissue. If the frequency is raised beyond this point, the vascular tissue becomes hotter than the fatty tissue. So in a relatively simple example it is possible by proper selection of frequency to heat one type of tissue at the expense of the other, or to heat both uniformly.

Let us consider another example. Now the electrodes are not placed in contact but are held at some distance away in the air from the mass of tissue. At low frequencies where there is no displacement current, it is impossible to produce any heat in the tissue since the conductivity of air is zero. At high frequencies, however, in spite of the zero conductivity of air it is perfectly possible to heat the tissue because while there is no conductive current in the air, conductivity being zero, there does exist a displacement current since air has a dielectric constant different from zero. All substances permit the passage of current at high frequencies if not the conductive, then the displacement current. Parenthetically we must say that these considerations apply only to conditions in which the magnetic field accompanying the current is to be neglected. This is true of all plate type applications at any practical frequency.

When we come to consider more complicated distribution of different types of tissues than the simple cases here discussed, matters become extremely involved and general statements are in order. As a general rule with the short wave and high frequencies, we are in a position to obtain more uniform heating of different types of tissue than with the low frequency. There are certain cases in which this is not true. For example, if we had two materials of the same conductivity but of different dielectric constants, the low frequency diathermy would heat them uniformly because it recognizes no effect of the dielectric constant whereas the high frequency current would heat them differently. With the exception of fat, however, all human tissue has practically the same dielec-

tric constant so that this consideration need not trouble us unduly. While this tendency to more uniform heating for higher frequencies is certainly present, it is nevertheless possible by the proper selection of frequency to heat a certain type of tissue more than others. This is what is commonly known as *selective heating*. For example, with a frequency of about thirty million, a maximum heating is produced in tissue of conductivity in the range of lung tissue, while with a frequency of seventy-five million, the maximum heating occurs in cartilaginous tissue. While these maxima exist, it nevertheless is true that as a general rule these maxima are not very sharp and short waves tend to produce a more uniform distribution of heat than long waves.

One factor in the problem has purposely been left out of consideration up to this point that is the question of the effect of size, shape and position of electrodes. The problem of heating of different types of tissue which we have discussed up to this point is sufficiently complicated in itself without at the same time attempting to take into account these geometric factors. They can be considered best by them-

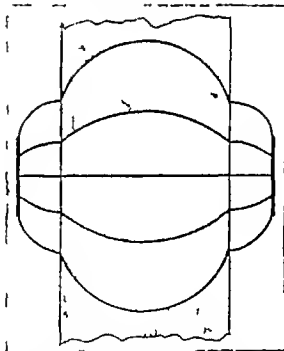

FIGURE 1 Showing the lines of electric induction in the case of a large homogeneous body exposed to the short wave field.

selves that is, we determine what the geometry of the situation can tell us with regard to heating of a homogeneous mass of tissue and then make use of our knowledge of differential heating as best we can in connection with any particular case. The geometric angle of the problem is best considered in a manner somewhat similar to that to which we have been accustomed in diathermy. We determine, if possible, the lines of flow in the substance to be heated considering it as homogeneous. We can then make any corrections we desire on the basis of the inhomogeneities existing. Since the heating in the high frequency field is much more uniform than in diathermy, the amount of such corrections will usually be considerably less.

There has been a tendency in the past in con-

sidering diathermy to imagine the lines of current flow to run directly from one electrode to the other. This is, of course, far from the truth. The field establishes itself accompanied by a spread through a large part of the medium subjected to the action of the current. In most cases with diathermy, the concentration of current is greatest at the electrode and diminishes in value as one enters the tissue. There is a tendency for more heat to be developed in the region between two electrodes placed close together, but if the electrodes are any distance apart, the heat developed near them represents practically all of the energy and the heat developed in the rest of the body is very diffuse. If the body to be heated were small compared with the electrodes and the electrodes were so arranged that the current must flow through the body to be heated, this heat developed would be uniform and would occupy the entire space. Similar considerations apply in short wave.

Figure 1 shows the lines of electric induction

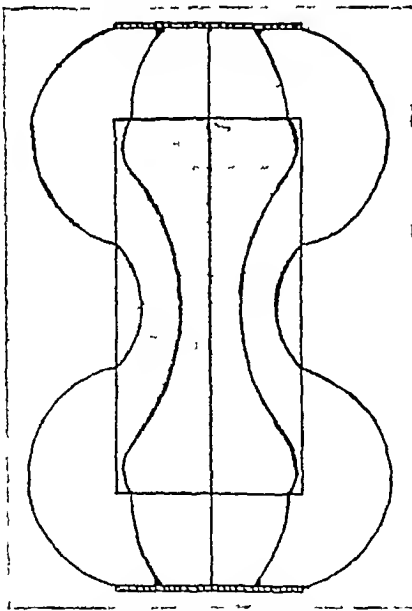

FIGURE 2 Showing the lines of electric induction in the case of a small homogeneous body exposed to the short wave field

in the case of a large homogeneous body exposed to the field between two plates properly spaced. The lines of flow and the heating in this case are essentially the same as that which would be obtained with diathermy, with contact plates of somewhat larger size than the plates used in short wave. The other case of the small body is shown in figure 2. Here the lines of induction tend to pull in and fill the body so that the heat is essentially uniform with possibly somewhat greater heating at the center. Such an effect can be produced with diathermy by using cuff electrodes. The field would then be very similar and the heating have essentially the same distribution.

With a homogeneous body, then, it appears to

be possible to duplicate with diathermy the distribution which would be obtained with short wave and the principal virtues of short wave lie in the ease of application since a direct contact is not required, and in the more homogeneous heating of the elements of a heterogeneous body.

The figure shows the heat produced by diathermy and short wave in a bovine thigh. The electrodes in each case were placed in the position

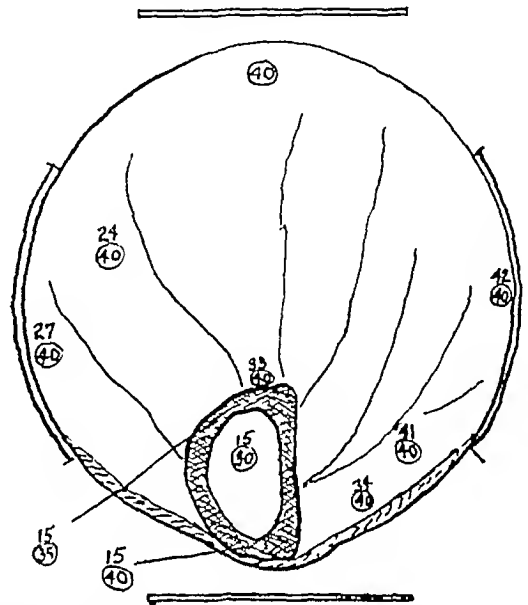

FIGURE 3 Showing the heating of a bovine thigh in the diathermy and short wave fields. Temperatures in degrees centigrade. Short wave determinations indicated in circles.

indicated for most uniform heat, the diathermy plate over essentially exposed muscle and the short wave plates across the bone. In the diathermy case, the temperature distribution was far from uniform. Near one electrode the temperature rose very much more than near the other because of a thick layer of fascia. The bone and marrow heated not at all. The temperature in fascia layers between the muscle was higher than the temperature in neighboring muscle tissues. The reason for these differences lies, of course, in the differences in conductivity between fascia, muscle and bone. With short wave, on the other hand, the heat of the muscle and fascia was essentially the same. The temperature of the bone was also raised to practically the same level, while the marrow remained relatively cooler. The entire impression is certainly that of much more uniform heat. The layer of fat surrounding one-half of the section was not heated unduly in the short wave field, whereas if it had been possible to pass diathermy in the same direction, this fat would have burned. (There was no skin covering this fat.)

These observations will indicate clearly that on the basis of the physical characteristics of the currents and of animal tissue, it should be possible to exert a more uniform heating effect

upon the tissue lying beneath the surface of the body by means of the short wave than by diathermy.

Living tissue differs greatly from dead tissue in that it possesses a rapidly circulating medium which can carry heat away from the region where it is produced. The most direct way of determining the actual temperature produced within tissues is to measure it by means of thermocouples. We performed such experiments on normal subjects. We applied diathermy and short wave currents to the thigh by means of cuff electrodes. We have previously

FIGURE 4. X-ray showing position of intramuscular and subcutaneous thermocouples in thigh.

described the results of temperature determinations when diathermy was applied by means of cuff electrodes to the leg.¹

We conducted two experiments on two different subjects. The intramuscular, subcutaneous and skin surface temperatures were taken before the application of the heating current. The machines were then applied for a period of twenty minutes, the current turned off, and the thermocouple needles reinserted immediately afterwards into the same area. Readings were then continued for an interval of several minutes. The subject in experiment No. 1 was bigger than the subject used in the second experiment. The thigh measurements indicate this, that of the first man being about fifty-four cm in circumference, and that of the second about forty-four cm in circumference.

In the first experiment, the short wave was applied in the morning. Diathermy was applied to the same thigh of the same subject in the afternoon. The intramuscular temperature before the diathermy experiment was 100°F, as

contrasted with 97.7°F before the short wave experiment. In other words, although more than two hours had elapsed between the time at which the short wave machine was shut off and the time at which the temperature determination was made prior to the diathermy application, there was still some elevation of intramuscular temperature. It is, of course, possible that this persistent local temperature elevation might have been due to the reaction to the trauma caused by the insertion of the thermocouple needle. In the first experiment, the greatest temperature rise was in the subcutaneous tissue when diathermy was applied, and next in the subcutaneous tissue when short wave was used. The intramuscular temperature rose more than five degrees F, following the application of short wave, and only about two and one-half degrees F, following the application of diathermy.

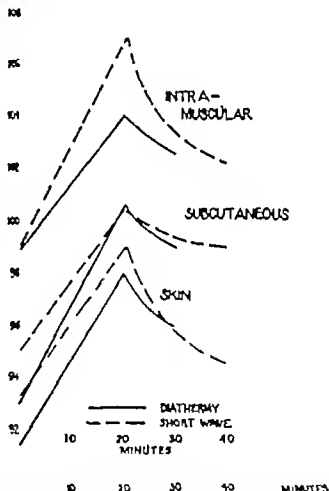

FIGURE 5. Cutaneous, subcutaneous and intramuscular temperature determinations in thigh of living human subject before and after exposure to twenty minutes of diathermy and to twenty minutes of short wave current. Cuff electrode technique. Temperatures in degrees Fahrenheit.

In the second experiment, the greatest rise (about eight degrees F) occurred in the intramuscular temperature following the application of the short wave current. The next highest (about seven and one-half degrees F) occurred in the subcutaneous tissue following the application of diathermy. The rise in the subcutaneous temperature after short wave amounted to about five and one-half degrees F, while the intramuscular following diathermy was only about five degrees F.

In the second experiment, the first application was that of diathermy. It was made to the left thigh. About twenty-five minutes after this ap

plication, the short wave was applied in a similar manner to the right thigh. This experiment was a more satisfactory one because the intramuscular temperatures prior to both diathermy and short wave were almost the same.

From these experiments we can state that with the technique employed, the short wave applications can cause an elevation of intramuscular temperature as high as and higher than diathermy when applied in the same fashion. The elevations of temperature produced by diathermy in our experiments are about the same as those reported by Mortimer and Osborne.² The short wave temperatures are decidedly higher.

Whether there be any effect other than that of heat on applying the short wave current has not been determined with absolute definiteness, but a possibility does exist, as indicated by the work of D'Arsonval and by the work of Mellon, Szymanowski and Hicks who showed the attenuating influence upon diphtheria toxin.³ In these experiments the heating effect of the current was carefully excluded.

There are many biologic changes which occur as a result of temperature elevation of living tissues. We have referred to some of these.⁴ They include the production of an active hyperemia, with its dilatation of blood vessels, increased permeability changes in capillary and intercellular pressure values,⁵ chemical changes such as those in pH, and carbon dioxide and oxygen content,⁶ increased phagocytosis,⁷ etc.

From the point of view of the practicing physician and surgeon, the most important consideration is the determination of the clinical results obtained by the use of this current. The consideration of the physical and physiological changes is important in order logically to explain the clinical changes, but, after all the proof of the pudding is the eating thereof. Clinical impressions, in order to become definite, must be based upon observation on thousands of cases by many different men over a period of several years. Inasmuch as this therapy is relatively new, the number of cases treated has not been sufficiently large, nor the length of time sufficiently long, to permit anything aside from impressions. We have treated well over one hundred cases during the past two years. We have gained the impression that, in general, the short wave current may be used for the treatment of those conditions for which medical diathermy has shown itself to be of value. These conditions include such pathologic states as bursitis (especially about the shoulder joint), traumatic tenosynovitis, myositis, myofascitis, sprains, and arthritis. The types of arthritis treated with most satisfactory results are the traumatic and gonorrheal. The problem of infectious or rheumatoid arthritis is complex because of the focal and systemic factors. Local joint heating is one of the adjuncts in the treatment of this condition. In many of our pa-

tients the vertebral and the sacroiliac joints were involved. Our impression is that the results obtained by the use of the short wave current in the treatment of these conditions are superior to those obtained by the use of diathermy. We must not forget here as in all other conditions where heat is applied, the question of dosage should be kept in mind. We have, for example, observed aggravation of the pain about the sacroiliac joint following short wave treatment when the reaction to diathermy was decidedly less severe. The ability to create a greater amount of heat may be a disadvantage. For this and for other reasons, such as its surgical usefulness, it is reasonable to conclude that diathermy apparatus will not at the present time be replaced by machines giving short wave currents.

Our experience leads us to believe that the use of heat is of value in the treatment of paranasal sinusitis. We have seen individuals suffering from pains due to the involvement of ethmoid, sphenoid, frontal and maxillary sinuses secure rapid and marked relief following the application of diathermy applied by means of a specially constructed cast and following the use of the short wave currents. Many of these patients had for years been under treatment by nose and throat specialists of good standing and of undoubted ability. The nose and throat specialist should add this form of treatment to whatever else he believes to be of value in treating both acute and chronic sinusitis. Here, as elsewhere, the surgical principle of adequate drainage is an important one.

Many of the proponents of the short wave current in Europe have been particularly enthusiastic about its use in the treatment of infections. We have treated such diverse infections as axillary abscesses, infections of the finger, carbuncles of the neck, infected pilonidal wounds (after surgical enucleation), furuncles of the nose and face, infected cervical glands, chronic osteomyelitis (with drainage) and chronic purulent otitis media. Our impression is that the short wave current is of great value in the treatment of these conditions but must be used with surgical judgment.

It appears to be possible frequently to abort localized acute infections if they are treated in their early stages. Very often, however, if the inflammatory process goes on to suppuration, this suppuration seems to develop much more rapidly than it would without the treatment. When it does occur, it is our practice to provide drainage surgically unless such drainage takes place spontaneously. We think it wrong to treat acute suppurative processes without drainage. There is nothing new in the application of heating procedures for the treatment of local infections. Warm poultices have been used for many years. We have used the conductive, the convective and the converse heat from radiant sources for a

long time. It is therefore not necessary to ascribe any specific effects of the short wave currents upon microorganisms to explain the beneficial influence of a procedure which creates heat in the involved area with a thoroughness greater than any other measure used thus far. It is our definite impression that when drainage does exist, the infected process usually appears to heal very much more rapidly following short wave applications than with any other forms of treatment we have used heretofore. It has generally been considered that diathermy is contraindicated in the treatment of acute local infections. It would, of course, be a matter of practical difficulty to apply diathermy electrodes over such acutely inflamed areas.

Short wave currents have the advantage of ease of application not only over areas of infection but also over other regions such as the ear, the eye, the nasal sinuses, and the lower spine.

To achieve the best results it is necessary to have some knowledge of the technique of the application of these currents. The condenser plates should be held at a distance of about one half inch to one inch away from the area treated. Schliephake¹ insists that no material be interposed between the condenser plates and the surface of the body (aside from his glass shoes), while others feel that good results may be obtained if the condenser plates are kept away from the surface by means of felt pads or towels. It is best to remove the clothing from the part to be treated and care should be taken that there is no metal in the field.

An agency such as this which is sufficiently potent to produce considerable elevations of local tissue temperature is not devoid of the possibilities for harm. Burns can be produced if the application is made carelessly or to a region which is anesthetic so that the patient cannot experience the sensation of thermal discomfort. Such burns have been reported².

The enthusiastic statements which have been made concerning the therapeutic value of short wave currents have stimulated manufacturers of apparatus to place numerous machines on the market. Many of these machines are of very little, if any value. The fact that a neon bulb may be excited when placed in the neighborhood of the condenser plate is no indication of the therapeutic value of an apparatus. The practitioner may be guided by the Council on Physical Therapy of the American Medical Association which has been investigating the value of different machines made by various manufacturers.

DISCUSSION

CHAIRMAN LOWRY: Dr. Bierman has given us an excellent talk. He has a thought that I wish to pass on. He confided in me just before he came in that he takes the time and money necessary for running a home remains a bachelor and uses it for research. There are some young men here. Maybe you will follow his example. We need all the help in this field that we can get.

The meeting now is open for discussion of the last two papers.

DR. E. A. COBMAN, Boston: Mr. Chairman—I should like to ask the last speaker whether experiments have been done by putting in through a cannula, wax that will melt at given temperatures and then dissecting the specimen after the current has been used to find whether the wax has been melted.

CHAIRMAN LOWRY: Would you like to answer that now or at the end?

DR. BIERMAN: Possibly I will answer all the questions at the end.

DR. LOUIS FELDMAN, Boston, Mass.: I have made use of the so-called "Short Wave" generator twenty-four meter wave length type for about seven months. First I experimented upon small animals in vitro and in vivo followed by over 1,000 treatments on the living human body. The indications for its use were the same as for classical diathermy, that is, wherever a deeper penetration of tissue heat was required. Two-thirds the dosage formerly used in conventional diathermy was taken as the standard in the treatment of my patients. The duration was fifteen or twenty minutes. Cuff method on extremities, contralateral pad method elsewhere. The dosage was also computed on the basis of square surface area of condenser electrode always taking into consideration the individual tolerance to heat.

The most satisfactory results were obtained by the interposition of one quarter inch felted cellulose cotton or toweling between the bare skin and the condenser surface, the pads being held in place by elastic bandages or sand bag abutments. The skin was observed at frequent intervals to see that there was no undue reddening, burning or discomfort or evidence of collection of moisture or pools of sweat. The radiations have a tendency to concentrate in such localities producing an increased density of current with resultant production of burns. This tendency has been minimized to a certain extent by proper technique as above described. With ordinary care common sense and judgment together with skill their likelihood to occur is less than with ordinary diathermy. The cuff method on extremities showed definitely more penetration through the tissues than by use of diathermy.

In the one thousand treatments given we did not get a single burn. But, previous animal experimentation and observation on patients treated elsewhere

muscle structures especially in relation to the bone. Calcification within muscle is well shown. Occasionally rupture of muscles may be seen, particularly if in a favorable position. Early muscle atrophy becomes apparent many times before there is a reduction in size of the involved muscle groups.

Soft tissue infections, particularly gas gangrene, may be detected in an early stage thus permitting surgery to be instituted relatively early.

While the solid bone detail does not show very early periosteal changes, inflammatory or malignant conditions become apparent. Very early callus formation is often shown if the part is not too heavy.

Gall bladder shadows after the Graham test are denser, an advantage with oral cholecystography. There is often improvement in delineation of soft abdominal shadows over the usual technique. Improvement may also be noted in radiography of the larynx.

Obviously in many instances soft tissue radiography should be undertaken in conjunction with a conventional technique. It supplements but does not supplant the latter. The cardinal principle is to obtain detail not outline of the non-calcareous structures.

Conclusions The principles of soft tissue radiography are briefly explained and indications for this type of radiographic exploration discussed.

DISCUSSION

CHAIRMAN LOWRY Dr Hampton of the Massachusetts General Hospital will open the discussion.

DR. AUBREY O HAMPTON, Boston As most of you know Dr Carty has been working on soft tissue radiography for four or five years and there is no doubt that he has done some valuable pioneer work in this field. Today he has presented some excellent examples of what can be done by careful x-ray studies of the skin, subcutaneous and muscle tissues. I am particularly impressed by the quality of his lantern slide reproductions because the technique of soft tissue radiography is difficult and reproductions on lantern slides must be even more difficult.

I have not had much experience with radiography of the more superficial soft tissues except in so far as they are related to diseases of the bone. Roentgenologists can no longer interpret films of the abdomen by simply stating "There are no visible areas of calcification," because the soft tissues are also visible and must be interpreted. It is surprising

how frequently tumors of the female pelvis, retroperitoneal masses and other soft tissue abnormalities are clearly demonstrated on a good radiograph of the abdomen.

CHAIRMAN LOWRY Is there any further discussion of this paper? Any questions? Have you anything to add, Dr Carty?

DR. CARTY I would like to say that Dr Hampton brought out a very important point. There is a great deal of soft tissue detail that can be seen on the conventional bone radiograph. I think we should become more soft tissue minded. We have found it helpful to view these films by lights of various intensities and of various wave lengths.

I would like to reiterate a point Dr Hampton made regarding showing soft tissue radiographs by lantern slides. We had to make over 100 lantern slides to obtain those I showed you. However, soft tissue radiographic technique itself is not overly difficult.

We are very much interested in this work, and feel that here is a field to add to the usefulness of roentgenologists. In several instances, for example, we have been able to make a positive diagnosis of a soft tissue tumor. We feel the work is in its infancy, and we need help in pursuing the various angles which this study I believe opens. I thank you.

CHAIRMAN LOWRY We are very grateful for each of the speakers who came here today. This has been a good meeting. We are sorry we did not have the fourth paper.

I would like to say that we are starting something new this year. We have an exhibit under Physical Therapy Section, showing massage and a few of the simpler forms of physical therapy, primarily to get the general practitioner interested in the subject.

The Nominating Committee has brought in the two names presented to you just previous to the reading of the last paper. Are there any other nominations from the floor? (No response.) If not, do I hear a motion about these names?

DR. HAMPTON I move that the chairman cast one ballot.

(The chairman cast a ballot for the nominees.)

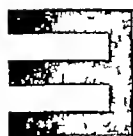

CHAIRMAN LOWRY Dr Philip Cook will be Chairman for next year and Dr William G. Curtis the Secretary. I so declare them elected. Dr Cook, will you stand up? Dr Curtis?

DR. COOK, you are now the chairman. Fellow members, he has done a good job as secretary this year, and will make us an excellent chairman.

DR. COOK Gentlemen, I want to thank you most heartily for this honor. I will try to carry on as well as my able predecessor. Is there anything further to come before the Section? If not, I will declare the meeting adjourned.

BOSTON TEST CHART

50 FEET

40 FEET

30 FEET

20 FEET

SUGGESTIONS FOR USE OF CHART

For testing the vision of children in the school, the chart on the right side is especially adapted, and for the following reasons:

The symbols conform more nearly to physiological requirements for objects than do letters, and more satisfactory results have followed wider spacing of the smaller symbols.

The chart is practically unlearnable.

It can be used in testing pre-school age groups, illiterates, mutes,

and its size will permit it to be kept clean in an envelope, without staining.

The chart should be hung on an easel, blackboard or other device, in a window, but not in direct sunlight, at right angles to the window. (It might even be hung in window-casing.) If one end of the chart is brighter than the other, hang the chart near a window at the brighter end. Height of chart should be about level of average child's eyes.

If there is glare from windows between the chart and the child, the lower half of window may be covered, or shade drawn. This does not bother unless the child, standing at the twenty foot line, is directly in front of a window. (Glare is a brightness, within the field of vision, of an excessive character as to cause discomfort or interfere with vision.)

Your assistant now points to any symbol on the top line, and the child semaphores the direction in which the arms point. If correct, the assistant then points to any symbol on the second line, and so on to the fourth line where at least two symbols (one with arms vertical, one with arms horizontal) must be seen before vision of 20/20 is recorded. The left eye is tested in the same manner. Supporting the child's head enables you to detect any head movement which might prevent the child to see with the covered eye.

If the child can see only to the third line, vision is recorded 20/30; that is, if to the second line 20/40, and if only the largest symbol 20/50.

If the largest symbols cannot be seen, walk the child toward the chart (being sure to keep the other eye covered). Instruct the child to stop when he can see the largest symbols. When this is done, note the distance from the chart in feet, and record the vision using this distance as the numerator and fifty as the denominator, because the largest symbols can be seen by a normal eye at fifty feet. If, for example, the largest symbols can be seen ten feet from the chart, vision is

2 Measure accurately a distance of twenty feet from chart, along a windowed wall, placing a thumb tack or chalk mark on floor every five feet. Procure one or more stiff cards, 3 x 5 inches.

3 Having arranged for some one (teacher, nurse, or child) to point to the symbols, have the child toe the twenty foot line. Always test the right eye first. If the child wears glasses, ask if he has better vision with or without glasses. If better with glasses, test with glasses on, recording vision thus:

Right eye	Left eye	with glasses
20/20	20/30	

If better without, test with glasses off.

4 Take position to the side and slightly behind the child, cover left eye by holding the longer side or edge of card against side of the nose with the left hand, support the child's head lightly with the right hand.

ROUTINE VISION TESTING OF SCHOOL CHILDREN,
A PLEA FOR STANDARDIZATION

BY JAMES J. REGAN, M.D.*

VISION testing of school children as part of the school program has become so general that it seems a pity not to take steps to standardize this important school function. By methods now in common use, uniformity of findings is impossible, with the result that children with defective vision are not detected, and many with normal vision are said to be defective, the former making it more difficult for the child to acquire an education, and the latter rousing the ire of indignant parents who are put to trouble and expense needlessly.

The most important single factor in the correct estimation of visual acuity is the test object used. With the selection of a test chart which will insure uniform results, only trivial faults in technique of conducting vision tests remain as a cause of error. These need only be called to the attention of the examiner and for this purpose, the writer has printed on the reverse side of a new chart suggestions for its use, with illustrations.

Regarding the importance of the selection of a test object H. Kuehler (1835 or 1836), according to Ewing¹, was the first to suggest a standard for testing vision which could be employed by anyone, anywhere. Kuehler recommended

(1) "a measure of vision for those with weak eyes, and a measure that would be common to all practitioners",

(2) "a measure of vision by which the same patients could be tested at varying intervals of time and a measure of vision that would be recognized by all physicians as being exact."

This is just as true now, a hundred years later, as when the pronouncement was made.

On this important point, Snellen² says "As the most suitable objects for measuring the visual angle we may select sets of three parallel lines and the correspondingly distinct figures, which can be geometrically deduced from them. These figures should be square, measuring, as far as possible, the same both vertically and horizontally and having inter-spaces equal in thickness to their component lines. Everything which might facilitate guessing at the shape of the figures must be avoided etc."

Regarding the development of a variety of test objects, he wrote: "Finer types, less complicated letters, and forms which are not square have been proposed, thus losing sight of the principle which is particularly insisted upon,—VIZ.,

that the letters should as far as possible, possess the same order of distinctness as our three equally thick parallel lines with equal interspaces. It is indeed a pity that it appears to be impossible to keep to one uniform scale by which visual acuity shall be tested."

The writer agrees that Landolt's broken ring is superior as a test object to Snellen's three parallel lines or its modification developed by Pergens³ which resembles the letter E, but its use with school children is not satisfactory.

Of capital letters used as test objects, Jackson⁴ said, "as a test for visual acuity they probably afford the poorest and most inaccurate standard on which any scientific observations are now based. They possess two essential defects as a scientific standard.

"First, the different letters, when made as uniform as possible, are visible from different distances,

"Secondly, they can readily be committed to memory."

After studying the problem for two years, the Committee on Standardizing Test Cards for Visual Acuity⁵ reported as follows: "The work of the Committee has served to emphasize the unsuitability of the alphabet as a standard of visual acuity."

They found the letter B had about the same visibility as Landolt's broken ring, while all other letters were more easily seen, and L most easily visible. A rating table based upon visibility gave L 71, T 74, O 80, E 85 H 92, B 100.

The same Committee reporting in 1917⁶ reduced the value of letter L to 62 and increased B to 115, compared with the broken ring.

Of letters of the alphabet, only eighteen were found suitable but even these eighteen have different degrees of visibility. Manifestly the fewer letters used, the more easily they can be committed to memory. Cowan⁷ suggested modifying the shape of certain accepted letters in an attempt to have them conform more accurately to the Snellen scale, but, in doing so, altered the form to such an extent that they were no longer familiar to the patient. Familiarity with the letters of the alphabet incidentally, is the chief reason for their continuance in favor as test objects. Regarding the non-serif E, which has a very high rating as a test object and which also has been used, pointing in different directions, as an illiterate symbol, Cowan has this to say: "The short middle bar changes the outline which aids in determining the position of the symbol, thereby reducing its value as a test object."

Regan, James J.—Ophthalmic Surgeon-in-Chief, Boston City Hospital. For record and address of author see "This Week's Issue" page 544.

The 1916 report of the Committee on Standardizing Test Cards for Visual Acuity⁵ mentions several factors which resulted in varying visibility of letters on several charts, one of which was "proximity of neighboring letters", and while no further mention was made of this factor, it has been the writer's experience that children without eye symptoms and with no refractive error could see the symbols on either end of the twenty-foot line, but failed to see the symbols between. It appears then that while most test charts have been printed with a five minute interspace separating five minute test objects, there is nothing contained in Snellen's original monograph⁸ suggesting spacing of symbols, and a larger number of children, with normal eyes, have been able to see all the symbols on the twenty-foot line when a chart, with twenty-foot symbols spaced twelve minutes apart, was used.

Inasmuch as the development of the Boston Test Chart (the test object was suggested by Ed Pergens of Belgium, 1863¹) as well as the technic for conducting vision tests resulted from work done in the schools of Boston, the use of the chart and the method of conducting tests is especially recommended for testing vision of school children. Note—The Department of Education, Commonwealth of Massachusetts, has been furnishing Pergens' symbol charts to the schools since 1917.)

The chart measures 8" x 10½", is printed on 12-ply stock, its size permits its being kept clean in an envelope, without bending or breaking, when not in use. Its front surface contains four lines of test symbols, accurately drawn to Snellen's scale, which resemble the letter E and each symbol points in one of four directions, up, down, right and left. The upper line contains symbols which subtend an angle of five

minutes at fifty feet, the second, third and fourth lines contain smaller symbols which subtend angles of 40, 30 and 20 feet respectively. The reverse side of the chart contains suggestions for the use of the chart, with three illustrations, which we feel make it ideal for the teacher, nurse, medical inspector, or other school official conducting the test, to refresh their memories upon the important points. This is deemed desirable inasmuch as, in most cases, the chart is used but once a year.

Snellen stated that "The most suitable illumination for the examination of visual acuity is average daylight, or artificial light of about the same intensity."⁹

The writer has found average daylight, which according to Luckiesh¹⁰, ranges from 100 to 300 foot-candles at the window casing, most satisfactory, is available during most of the school day, and requires no special apparatus.

A copy of the chart, with text and illustrations on reverse side, is offered herewith.

MASSACHUSETTS MEDICO-LEGAL SOCIETY

ARSENIC IN HUMAN TISSUES AND FOOD ANIMALS*

I So-Called Normal Arsenic

BY WILLIAM F. BOOS, M.D.,† AND A. BENJAMIN WERBY, B.S.†

INTRODUCTION

IS arsenic a normal constituent of the human body? This question was first propounded in 1841, by Orfila¹, whom we may well consider the father of modern toxicology. After that the subject of normal arsenic received little attention till toward the end of the nineteenth century when the French school, represented chiefly by Gautier^{2, 3, 4} and Bertrand⁵, became actively interested in the problem.

The results obtained by the French school, which tended to show that arsenic was normally present in a number of human organs, were strongly contested by the German school, of which Hódmoser⁶, Ziemke⁷, Cerny⁸, and Kunkel⁹ were the chief exponents. The German investigators claimed that although traces of arsenic may be found occasionally in some human organs, that more often it is entirely absent and could not therefore be considered a normal constituent of the human system.

The controversy seems to have ended with Kunkel's declaration in 1905, that as far as forensic medicine is concerned, there is no such thing as normal arsenic. We believe that this

*Read in part at the Meeting of the Massachusetts Medico-Legal Society June 4 1935

†Boos William F.—Toxicologist for State of Massachusetts
Werby A. Benjamin—Chemist Research Laboratories New York and Boston For records and addresses of authors see 'This Week's Issue' page 544

statement holds good today, and shall refer to it later. Kunkel does not deny the possibility that traces of arsenic may be present more or less constantly in the organs but he does not attach any importance to it. Since the days of the controversy, much work has been done on the subject and we think that the consensus among modern authors is that the French school did not prove its contention of normal arsenic and that the German school did not disprove it.

In 1923, Billeter and Marfurt¹⁰, two Swiss investigators, employed a painstaking and very sensitive method which enabled them to find minute amounts of arsenic in all the human tissues which they examined. Their work was done on twenty-four cadavers of persons ranging in age from birth to seventy years. They estimated that arsenic makes up about one ten millionth of the body weight. The body of a person weighing 150 pounds would therefore, contain one tenth grain of arsenic. They found further that the quantity of arsenic in the tissues increases with age, a finding which in a sense we can bear out.

In order to demonstrate the presence of arsenic in the tissues, these authors used as a rule twenty grams of material. Now, of course the more material used, the better the opportunity to find arsenic. However, for forensic purposes a proceeding such as theirs would not be suitable, since the object of a forensic investigation is to demonstrate either poisoning by arsenic or the absence of arsenic in the tissues. That is to say, the method used must show either an amount of arsenic which is incompatible with life or none at all. This object may be attained in practice by using only five grams of material for each determination. With this amount of material normal tissues yield a negative result, while those of a victim of arsenical poisoning yield a substantial reading for arsenic in each organ. In this sense, therefore, the dictum of Kunkel that the presence of so-called normal traces of arsenic in the tissues does not affect the results of forensic investigations for this metal, comes into its own.

Billeter and Marfurt have demonstrated that traces of arsenic are actually present in all human tissues, but their work has not thrown any light, so far, on the problem why the arsenic should be there. The term "normal" implies that the presence of arsenic in the tissues is necessary for the proper functioning of the body cells, that the arsenic is not "accidental" and is not due merely to the fact that all food and drink contain so much of the poison that it is impossible for the system to be at any time free from it.

Guthmann and Grass¹¹, who used an exceedingly hypersensitive method for the analytic determination of arsenic, tend to show that the metal does play some part in normal life processes. They found that (1) the blood of

all women contains on the average 0.638 parts per million of arsenic during the intermenstrual or "normal" period, with but slight variations (2) at the time of menstruation the arsenic content rises on the average to 0.925 parts per million, (3) with pregnancy the arsenic content of the blood rises on the average to 1.44 parts per million, (4) the arsenic content of the blood reaches its highest point between the fifth and sixth months of pregnancy, (5) that after that it diminishes slowly, but contains throughout pregnancy more arsenic than the blood of the non-pregnant woman, (6) the arsenic content in the blood of women suffering from carcinoma is forty-three per cent higher than that at the intermenstrual period of normal women.

Based on the fact that the arsenic in the blood is increased by menstruation, pregnancy and now growth the authors assume that the increase of arsenic is directly related to the process of growth and cell proliferation, and that there may be a causal connection.

If the facts found by Guthmann and Grass are borne out by future investigators, their work will rank as fundamentally important. At present, however, their results cannot be accepted without reservation.

Several years ago, we became interested in the deposition of arsenic in hair and bone. From a forensic point of view, the arsenic in hair has no value in acute death from arsenic, but that in the bone is very important.

Considering first the hair, we find, to begin with that all hair contains arsenic, that is to say, arsenic determinable by ordinary forensic analysis. This arsenic is being constantly excreted by the hair which constitutes an important organ of elimination for this poison, but the expulsion of arsenic by hair is a comparatively slow process at any time. The arsenic is taken up by the roots of the hair where it is fixed, and, as the hair grows any of the metal which has been absorbed grows out with it. The growth of the hair is on the average, six inches a year, or one eighth inch a week and less than one sixteenth inch in three days. The three day period is chosen by us because deaths from acute arsenical poisoning may occur in anywhere from a few hours to three days after the ingestion of the poison. It will be seen that a maximum growth of hair of one sixteenth inch in acute arsenical poisoning, will not be high enough out of the scalp to be removed by cutting.

ARSENIC IN HAIR

A sample of hair was taken at an autopsy performed by Dr. John Paul Reardon, Medical Examiner of Middlesex County, on Miss Alice Porter. The tress of hair was thirteen inches long. It was divided into three equal parts.

proximal, midway, and distal The results are given in table 1

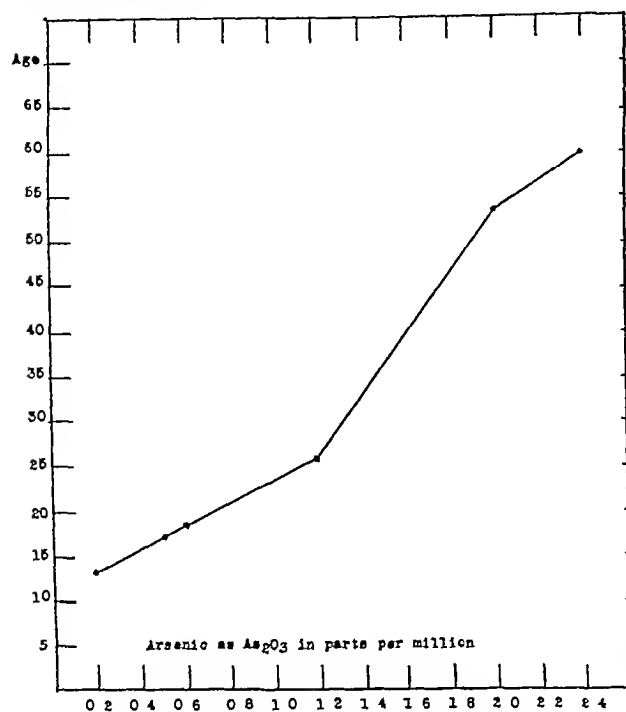

FIGURE 1 Arsenic in Human (Female) Hair

TABLE 1

Part of Hair	Arsenic as As_2O_3 , in parts per million
Proximal	14
Midway	24
Distal	20

From another autopsy performed by Dr. Rear-don on Mrs. Elizabeth Stollmcker, samples of hair were taken and examined. The results are listed in table 2.

TABLE 2

Part of Hair	Arsenic as As_2O_3 , in parts per million
Proximal	30
Midway	31
Distal	27

The very high values obtained in these two cases, prompted us to investigate the hair of healthy living persons, who had never been subjected to arsenic therapy. We analyzed the hair of girls of thirteen, seventeen, eighteen, and twenty-six years of age, and that of a woman aged sixty. In these samples, merely the distal hair was examined. The results are given in table 3.

Several examinations of hair taken from fur, which were made by one of us (W.), did not show any appreciable quantities of arsenic. The

probable reason for this is to be found in the environment of the fur bearing animals in which spraying with arsenic compounds does not occur.

TABLE 3

Name	Age	Arsenic as As_2O_3 , in parts per million
J. W.	13	0.2
P. M.	17	0.5
G. P.	18	0.6
S. M.	26	1.2
A. Porter*	53	2.0
M. B.	60	2.4

*We have included Miss Porter's hair (see table 1) but have omitted Mrs. Stollmcker's hair (table 2) from table 3 because the arsenic in it was abnormally high and suggested some arsenical medication during the last year or so of her life. The samples of hair recorded in this table (3) show the interesting fact that the deposition of arsenic in the hair increases directly with age (figure 1).

SOURCES OF ARSENIC IN FOOD

What is the cause of this increased amount of arsenic in hair? The only logical answer is that the food which we eat today contains more arsenic than was formerly present in food. Remington¹² has noted that the arsenic of the body is usually attributable to food, because of (1) chemical treatment in manufacture, (2) absorption by plants from the soil, (3) presence in sea food and (4) the widespread use of arsenical sprays in America, this having an important bearing on the point of the arsenic mechanically carried and the absorption by the plant as well. Headden¹³ found that our virgin soils contain from two and one-half to five parts per million of arsenic and the underlying marl four to fifteen parts, and that the crops grown on such soils, and the animals fed on these crops contain arsenic. Other investigators have reported the finding of arsenic in soils of other localities.

In 1933, Myers and others¹⁴ published their results of the analyses of a number of the common vegetable foods purchased in city markets. These are summarized in table 4, and are recalculated to arsenic as arsenic trioxide.

TABLE 4

Variety	Arsenic as As_2O_3 , in parts per million
Broccoli leaves	0.3—0.66
Broccoli	0.00—0.15
Beet greens	Traces
Cabbage	0.00—0.19
Carrots	0.00—0.17
Celery	0.00—0.26
Egg plant	0.00—0.21
Lettuce	0.00—0.17
Lima beans (green)	0.00—1.25
String beans (green)	0.00—0.05
Fruits	0.00—0.22

In 1933 White¹³ reported the analyses for arsenic, made in the laboratories of the U S Food and Drug Administration, of a number of American marine foods. These results are extremely interesting, as they disclose a source of much arsenic. The data are recalculated to give arsenic as arsenic trioxide, and are shown in table 5.

TABLE 5

Variety	Arsenic as As_2O_3 in parts per million
Ood	2.0—5.4
Eels	2.6
Haddock (smoked fillet)	5.6
Mackerel (fresh)	1.9
Prawns	17.8
Sardines (canned)	1.5—2.9
Irish moss	2.0—8.4
Clams	1.5—2.6
Crab meat	2.0—11.0
Oysters	1.4—2.4
Lobsters	2.3—18.0
Shrimp	2.4—11.0

Much larger amounts of arsenic have been found by Chapman¹⁶, who reported the presence of relatively enormous quantities in crustaceans from the coastal waters of the British Isles. In lobster, he found an average of over 40 parts per million in the fresh meat, and in one sample as high as 110 parts per million were recovered.

The arsenic content of American cod liver oils offers some startling information. Holmes and Remington¹⁷ in their examination of twenty samples of American cod liver oils, comprising six geographical types, found very high amounts of arsenic. In view of the widespread use of cod liver oil, particularly by babies and young children, a large quantity of arsenic is being consumed by the very young. The average arsenic content of the oils is calculated to the trioxide and will be found in table 6.

TABLE 6

Source	Arsenic as As_2O_3 in parts per million
Massachusetts	1.9
Maine	1.8
Deep Sea	4.4
Nova Scotia	4.2
Newfoundland	3.7
Quebec	3.2

ARSENIC IN BONE

In the examination of human bone in poisoning cases, we sought to determine by the amount of arsenic present, what relation the quantity found bore to the duration of life after the poison was ingested. Our study seemed to show that when the individual lived only a few hours the amount in the bone was quite small, whereas the bone of those cases who had lived several

days, showed a substantial quantity of arsenic. Further to study this question, we examined the bones of food animals, purchased at a market. They included chicken, lamb, veal, pork and beef, and we have tabulated the results under table 7.

TABLE 7

Variety of Bone	Arsenic as As_2O_3 in parts per million
Chicken	2.8
Lamb	3.2
Pork	3.2
Veal	1.6
Beef	8.0

It will be noted that these figures are quite high, particularly that for the bone of beef cattle. The figure for veal bone is so much lower than that for beef bone because the animal is very much younger.

ARSENIC IN FOODS

We also examined a number of other foods for their arsenic content and listed the results in table 8.

TABLE 8

Variety	Arsenic as As_2O_3 in parts per million
Sugar (table)	1.4
Salt (table shaker)	0.01
Egg (hen) nearby	1.8
Starch (corn)	0.9
Cocoa	1.2
Calf's liver	0.4
Hamburger (beef)	1.0
Chuck (beef)	1.6

ARSENIC IN TOBACCO

We examined two popular pipe tobaccos and two well known cigarette tobaccos.

TABLE 9

Sample	Arsenic as As_2O_3 in parts per million
Tobacco (pipe) A"	12.3
Tobacco (pipe) B"	9.5
Tobacco (cigarette) C"	11.0
Tobacco (cigarette) D"	9.0

It is interesting to note that Remington¹⁸ examined pipe tobaccos and found arsenic present to the extent of from six to thirty parts per million, while Myers and others¹⁴ reported that in their examination of seven different tobaccos, the arsenic ranged from none to 1.65 parts per million. Our examinations of smoking (pipe) tobaccos agree with those of Remington, it would appear therefore that the results of Myers and others are perhaps too low and do

not show the true arsenic content of tobacco. Because of the daily use of vast quantities of tobacco in our lives, the figures as shown in table 9, tabulated and calculated to the trioxide, will be of value as indicating an important source of arsenic.

TABLE 10

HEALTH HAZARDS FROM ARSENIC AND LEAD

According to Myers and others¹⁴ the high arsenic found in broccoli, is indicative of its danger as a food. They state that some time ago, broccoli was served at a dinner given by a large group of medical men and approximately 100 of the individuals present suffered later with varying degrees of gastrointestinal symptoms, several had to be sent to the hospital. Arsenic was found in the broccoli. These authors further say, as a result of data collected over a period of fifteen years, that the elimination from the body of arsenic (and of lead) in any amount is of clinical significance, especially if there are symptoms which can be attributed to either metal. However, they feel that the amount of arsenic excreted is not a reliable guide concerning the extent of the physiological injury that has been wrought, because in some individuals there is a tendency to retention while, in others, there is rapid excretion. They believe that each and every one is exposed to metallic intoxication. According to them, some of the symptoms which should appear as a result of metallic poisoning from spray residue are fatigue, headache, vertigo, irritation of the eyes, pharynx and digestive tract, neuritis, dermatitis, blood vessel changes, possibly associated with vascular disturbances of middle and late life, pigmentation, paralysis, disturbances of locomotion, vomiting, dyspepsia, burning and gripping abdominal pain and cramps.

In a second paper we expect to show (1) the amount of arsenic found in individuals who have not been subjected to arsenic therapy, that is to say cases in which death was accidental or due

to natural causes, we shall report (2) our examinations of the various organs of food animals for their arsenic content, and (3) the complete findings of arsenic in most organs of a number of persons who died as the result of acute arsenical poisoning. In this paper we shall describe in detail the procedure which we employ for the determination of arsenic in organic material, as well as tests of the method.

SUMMARY

Arsenic is not shown to be a "normal" constituent of the human body, but is present in minute amounts due to ingestion with food. At the present time the arsenic content of food, both solid and liquid, is too large and must be viewed as a menace to the general well-being.

DISCUSSION

PRESIDENT GAY. Dr. Boos's paper is now open for discussion, and I am sure he will be pleased to answer any question which any of you may have.

DR. CANAVAN How much arsenic is there in tap water?

DR. BOOS I think the quantity is negligible. We have never made analyses of it here. But I want to make a great many examinations of this kind because I think it is important to continue this work. It is almost an open territory, a new field of work, and there is a great deal to be learned by the analysis of many things that enter into our lives.

A MEMBER You spoke of a good deal of arsenic being in cod liver oil. That is supposed to be a tonic and a medicine.

DR. BOOS Yes, but no one knew it was there as that is a very recent work done only a year ago. I think that none of the manufacturers had any idea that cod liver oil contained arsenic.

Ladies and Gentlemen—It is possible that the small amount of arsenic which Billeter and Marfurt found in the system and it was surprisingly constant in the organs serves a physiological purpose but for the moment, there is no proof of that. However there may be proof forthcoming that some of the arsenic which we have in the system belongs there but of course not all of it because we ingest excessive amounts of arsenic in our foods and liquids. Wine and milk contain arsenic. Milk is bound to contain it because the cows eat so much sprayed grass and hay.

DR. JONES I remember some years ago there was a death reported to this Society of a child who was thought, at the time, to have eaten some berries which had been recently sprayed with arsenate of lead. At that time several mooted cases were brought to the attention of this Society.

I have actually forgotten whether this child was autopsied but I think it was and no arsenic was found.

Previous to that, however, the State Police and I roamed through the area with two other children who showed us where the child had eaten the berries but we could find any particular berries except blueberries. There, we found great patches of luscious blueberries absolutely white with arsenate of lead. I watched afterwards and found that those berries were all picked and eaten. In fact, the next time I went there I found three women picking them. They informed me when I suggested that they might be uncomfortable after eating them that they had been eating them all along and they had not noticed any bad effects and they didn't see any harm in continuing to do it.

Now you brought up the subject about beef cattle in your paper but in southwestern beef there is no arsenic, I am quite sure. And beef cattle bones would come almost invariably from the west or the southwest.

DR. BOOS Most of the meat, of course does come from the west and southwest. I am told, however that western cattle are fattened for the market in New England where there is much spraying.

DR. JONES We went into the subject very carefully with the State Board of Health. We made it a regular study and could find no report of any cattle having died from that.

DR. BOOS I shall try to trace my information to its source. But there is a very interesting point which has been raised more recently. The Federal Government is beginning to think that the lead in arsenate of lead is almost as important as the arsenic itself.

DR. JONES I think it is

DR. BOOS That is why the Bureau of Chemistry is making such a strenuous effort to exclude lead from all sorts of food. They prohibited the sale of teas that were covered with lead foil as it was said that the tea took up a considerable amount of lead. I think the presence of lead is probably due to the scraping of the tea against the surrounding lead foil because we made some analyses for a client, and we found that the tea in the middle of the package was almost lead free.

The government is considering seriously the exclusion of some delicacies from France because they come in a soldered can which is considered to have quite an amount of lead in it. One product is sardines put out by a well known house.

Just now lead is the one thing that the Federal Government is most concerned with and it may be that lead is quite an important feature in the poisoning from lead arsenate.

Many of the garden vegetables are not sprayed with lead arsenate. They are sprayed with Bordeaux mixture the active principle of which is a copper hydrate. Small traces of this are often left, and you may have seen the light bluish green deposit on the celery. This deposit is entirely harmless.

A MEMBER With reference to Dr. Jones' remark as to the arsenic on the berries, in all probability the majority of people wash berries that is they soak them anyway partly for ordinary matters of cleanliness, and then a great many times to take away the little bits of leaves and branches and little things like that. Wouldn't that take away the possibility of arsenic?

DR. BOOS Have you ever tried to wash off the coating of urseenate of lead? It sticks and it is difficult to remove. You would almost have to rub each berry separately to get it off. You will notice that after heavy repeated rain there is still much white urseenate of lead on blades of grass and leaves.

DR. CANAVAN Do you think there is any flour used in spraying just ordinary flour?

DR. BOOS Yes flour is used to make this material sticky.

A MEMBER I would like to hear from Dr. Leary or Dr. Magrath on that subject, just informally if I could.

DR. MAGRATH I haven't anything very original to contribute as Dr. Boos has done all my analytical work and we have had many experiences in the very acute and more prolonged instances of arsenical poisoning.

I want to take this opportunity of thanking Dr. Boos for his valuable paper which is a real contribution. It seems to me, to the literature on this subject.

But, I haven't anything original of my own, because all the chemistry in cases of recent years where we have gone into the matter at all has been done by Dr. Boos. He has attended to all those matters.

DR. BOOS I forgot to speak to you gentlemen about autopsies. Sometimes it may be a question of poisoning and it would be very well in every autopsy if you would secure a sample of blood from the cadaver. The presence of arsenic in the blood of arsenical cases is very important, because it shows that the poison was still circulating in the blood, and that not all has been deposited in the organs. It is important, therefore whenever you refer a case to a toxicologist, for any kind of poisoning for that matter to give him blood if you can. It is one

of the most valuable of the organic materials for forensic purposes. This is true also of the urine.

Many of the cases that come to us have been embalmed and there is no possibility of obtaining liquid blood. In these cases clots removed from the great vessels will answer very well. In unembalmed cases the Medical Examiner has an excellent opportunity to draw blood from one of the veins.

A MEMBER I have done quite a little work in these matters, and sometimes when you can't find arsenic in the urine, can one still be excreting it for some time so that although you may not find it in the urine, you may find it in the hair? Have you any idea of how long it takes before it is so deposited?

DR. BOOS It is not deposited quickly. It takes time. It is deposited much more slowly in the hair than in any of the other organs.

In the Porter case, the proximal hair contained about one and fourtenths parts per million, the mid-way hair contained two and fourtenths parts per million, while the distal hair contained two parts per million.

A MEMBER And the same is true of the bones, isn't it?

DR. BOOS The manner of arsenic deposition in the bone has not been determined.

A MEMBER Then the chances are that if you don't find it in the urine, you will find it in the bones and the hair as the time passes?

DR. BOOS Do you mean arsenic taken as a poison in food or as medicine?

A MEMBER The possibility of there being arsenic there.

DR. BOOS I feel that you can always find it in the urine. We have found it in every case we have examined.

A MEMBER I would like to inquire how much blood it would be necessary to take?

DR. BOOS One hundred cc will do very well. If you can have more, of course, it is better.

You must be able to demonstrate in Court, with the wide-awake defense of today, that the system contained an amount of arsenic which would probably be fatal. That does not mean that you have to examine all the organs, but you should examine the blood, the internal organs, the bone, the skin and the brain. The muscles are very important, because they make up such a large bulk of the body. Even the fat contains an appreciable amount of arsenic. Then, by computing the matter that you have examined you still have a considerable part of the body weight not analyzed. But from your figures, and from the part that you did not analyze you estimate the arsenic to be such and such, whatever it is, for the whole body. Now, you may wonder why the body doesn't contain more than two and a half or possibly three grains of arsenic. I mean in the tissues themselves, you may find in the gastrointestinal tract a great amount in addition, but that arsenic has had little to do with a person's death directly, because it is excessive arsenic that has not been absorbed. It is only the arsenic taken into the system through the blood stream that counts. After the system has taken up two to three grains, it cannot take up any more because death results. The average found is two grains. In a big man, you will

probably find more and in a small woman, there may be less.

That is the reason for the uniformity of results in arsenical poisoning. As I have said, just as soon as the system has taken up enough to destroy the function of the cells, no more can be taken up. Up to that time, the system tries, very actively, to excrete the arsenic. That is why you always get a good test from cecal contents, the large intestine being one of the best of the excretory organs. In the intestine, you also find the arsenic which comes from the liver through the bile.

I don't know of any case of white arsenic poisoning since Dr. Magrath's case after the war, I mean the Archhook Case.

The kidneys try hard to excrete the arsenic, therefore the kidneys are usually high in arsenic content.

In the cases of acute poisoning, the skin is also high in arsenic because it is excreted in the perspiration.

The organs that are particularly high in arsenic are the liver, kidneys, large intestine, small intestine, lungs, skin and brain.

If you find much arsenic in the muscles, it means, I think, recent administration, because it is still circulating in the muscles. The longer a person has taken to die, the less arsenic seems to be in the muscles. If on the other hand, the victim died a short time after the dose was taken, there is an appreciable quantity of arsenic in the muscles.

DR. JONES You were speaking about the prophylaxis in arsenical spraying. I don't know whether the State law requires it, but very commonly, I have noticed that many trees are sprayed with arsenate of lead, and it is a deadly poison. I have seen this frequently.

DR. BOOS What I meant, particularly, was that operatives should be restrained in spraying, they should not spray indiscriminately over such a wide territory, covering orchards, lawns and pastures with the arsenic. What is needed is more scientific spraying confined to individual trees. The sprayers, as a rule, are not highly intelligent or efficient and they do a careless job. I have seen many cases where the spray went all over the windows of the house, through open windows into the house, and over the lawn, the flowers and vegetable beds. I think such careless spraying should be stopped.

Probably the arsenic in tobacco also comes from spraying.

DR. JONES It would seem as if it might be beneficial to find other material for spraying.

DR. BOOS That would be a matter for the chemists and entomologists. Arsenate of lead is very cheap, while other things are expensive, and perhaps not so efficient. I think, however, that something should be done to prevent the increased amount of arsenic in our foods.

There is one point I would like to consider regarding arsenic in food. Where does the lobster get its enormous amount of arsenic? All sea foods contain some arsenic, but most is found in those of the sea foods which belong to the crustaceans. Crabmeat is high in arsenic, so are prawns and shrimp, and lobsters, of course, top them all. It would seem that the crustaceans have a particular habit of taking up arsenic that the other fish do not show to nearly the same extent. Haddock, for example, is comparatively low in arsenic, even deep sea haddock is fairly low and so are most of the salt water fish. But none of them are scavengers like the crustaceans and it may be that animal and plant refuse which is thrown into the sea and is eaten by

the crustaceans is the source of their arsenic. The subject offers an interesting problem for the biologists. I have heard that fresh water fish do not contain as much arsenic as salt water fish. Perhaps then it is something that has to do with the sea itself.

A MEMBER How much is contained in sea water?

DR. BOOS I don't know

Perhaps you have heard of the cases of arsenical poisoning from beer that they had in London. The presence of the arsenic was due to the commercial sulphuric acid which they used to convert cornstarch

into glucose. The glucose was fermented to make the beer. Serious cases of poisoning resulted and there were some deaths due to large amounts of arsenic in the beer.

PRESIDENT GAY Thank you very much Dr. Boos. Now ladies and gentlemen in spite of what Dr. Boos says that we shouldn't eat eggs, pork cuts, drink milk and a lot of other things, and now it's lobster and beef, I want to announce right here that I haven't developed an antipathy to all these things. For I know that I am still going to eat lobster.

TRICHINOSIS IN BOSTON*

BY WESLEY W. SPINK, M.D.† AND DONALD L. AUGUSTINE, S.C.D.‡

TRICHINOSIS is one of the commoner parasitic diseases in New England. For the past three years, we have been interested in the clinical aspects of the disease, and in skin and precipitin tests as aids in its diagnosis. The results of these studies are presented in more detail elsewhere.^{1,2,3,4} The purpose of this paper is to discuss some of the epidemiological phases of the disease in Boston with a consideration of preventive measures.

It is of interest that the first case of trichinosis reported in America was by Dr. Henry Ingersoll Bowditch of Boston in 1842, and appeared in the pages of the predecessor of this *Journal*.⁵ Evidence of the disease was discovered at autopsy in a young man who died from a malignant growth. Bowditch states: "The muscles, and cellular membrane underneath them, seemed literally covered with myriads of minute white lines, looking at first sight like the ova of the common fly upon decaying animal matter."

Almost one hundred years have elapsed since Bowditch described his findings and, in the meantime, hundreds of cases of trichinosis have been recorded in American literature. While trichinosis is not so common as some infectious diseases, it occurs far more frequently than published reports indicate. In the statistical reports of infectious diseases which appear from time to time in this *Journal*, trichinosis is listed as a rare disease. This is in sharp contrast to the high incidence of the disease to which attention has been called recently as a result of observations made at routine postmortem examinations. Queen⁶ in Rochester, New York, found, after examining the diaphragms in three hundred and forty-four consecutive autopsies,

that fifty-nine (17.5 per cent) contained *Trichinella spiralis*. A similar study made on fifty-eight autopsies in Boston, Massachusetts, showed sixteen of the diaphragms, or 27.6 per cent parasitized. Riley and Scheinley⁷ studied the diaphragms of cadavers in the Anatomy Department of the University of Minnesota, and found the incidence in one series to be 17.9 per cent and 20 per cent in a second series. As a result of these studies, it appears that the incidence of trichinosis in three large cities is probably rather high. It might be pointed out that in Queen's series of cases no antemortem diagnosis of trichinosis had been made.

During the past three years, we have obtained clinical data in sixty-five proved cases of trichinosis in Boston. Most of these cases were observed at the Boston City Hospital, but through the courtesy of Dr. James H. Means, patients were also studied at the Massachusetts General Hospital. It is to be noted especially that most of these infections were sporadic and severe enough to require hospital care of the patients. If it could have been possible to observe other members of the families at home, the number of cases might well have been larger, as it is well known that individuals may be infected with the parasite and yet have few or no symptoms.

Of considerable interest in the study of these patients was the variable symptomatology. Standard textbooks of medicine, in discussing the symptoms of trichinosis, usually divide the clinical course into three stages. The first stage, that of the development of worms to maturity in the intestine, includes nausea, vomiting, diarrhea, and abdominal pain; the second stage, the period of dissemination of the larval worms as marked by muscle tenderness, edema of the eyes, and eosinophilia, while the third stage, or the period of encystment, is that of convalescence. But such was not the clinical course in most of the sixty-five cases. One patient was observed having only edema of the eyes and a fever. There were no gastrointestinal symptoms or muscle tenderness, and yet a biopsy of the gastroc-

*From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, the Department of Medicine (Harvard Medical School), and the Department of Comparative Pathology (George Fabyan Foundation, Medical School and School of Public Health, Harvard University, Boston, Massachusetts).

†Spink, Wesley W.—Assistant in Medicine, Harvard University Medical School. Augustine, Donald L.—Assistant Professor of Hematology, Harvard University Medical School. For records and addresses of authors see "This Week's Issue," page 444.

nemius muscle, when examined microscopically, showed four larvae per high power field. Another patient had an unexplained fever as the only complaint. Some patients had no gastrointestinal symptoms, yet they developed severe muscle pains. Others had gastrointestinal symptoms but no muscle pains. A most puzzling case was that of a young colored girl who developed a fever, and marked weakness of the muscles of the back, arms and legs. She was under observation for poliomyelitis until examination of blood smears showed a marked rise in the number of eosinophile cells. Microscopic study of a muscle biopsy revealed several recently encysted larvae. During the whole clinical course, she had no edema of the eyes, gastrointestinal symptoms, or muscle tenderness.

Since the disease manifests such a variable symptomatology, the diagnosis of the sporadic case may be very difficult. We have found the most valuable aid in diagnosis to be the presence of eosinophilia. Many persons were first suspected of having trichinosis because of the blood picture. Perhaps the reason why trichinosis is not recognized more often is that the routine examination of stained blood specimens is not done frequently enough in private practice or even in hospitals. The diagnosis may be made more difficult when eosinophiles are absent in the blood smear. One of us (W W S*) has observed that eosinophiles may not be found in the blood of either trichinous animals or human beings when a secondary pyogenic infection is present. Thus in two of our patients who were under observation for one to two weeks before the correct diagnosis was made, it was eventually found that a secondary pyogenic infection had suppressed the eosinophiles, and it was only when the secondary infection subsided that eosinophiles appeared in the peripheral blood. Skin and precipitin tests have been very useful in the diagnosis of suspected cases. The skin test usually becomes positive after the second week of the disease, and the precipitin test between the third and fourth weeks.

Briefly, the diagnosis of trichinosis depends upon a careful history of the patient's illness, a complete physical examination, repeated examinations of blood smears for eosinophiles, and the use of skin and precipitin tests. In our experience looking for the larvae in the blood, spinal fluid or muscles is a waste of time and unnecessary if the foregoing procedures are carried out.

An analysis of the epidemiological data in these cases is desirable, as an aid in controlling the disease. Only one of the sixty-five cases terminated fatally. This occurred in an Italian laborer who had eaten about four pounds of raw salt pork over a period of several days. Death

was due to an acute myocarditis and bronchopneumonia.⁴

The distribution of the cases according to parentage is seen in table 1. It is interesting to note that no Germans are included, but this may be explained on the basis that there are relatively few Germans in Boston. Most epidemiological studies have pointed out that a large proportion of cases occurred in Germans, due to the fact that they consume a great deal of raw pork. Another point of interest is that not all the cases occurred in people of low intellect and social status. Seven cases occurred in the families of two prominent physicians.

TABLE 1
DISTRIBUTION OF SIXTY-FIVE CASES OF TRICHINOSIS
IN BOSTON ACCORDING TO PARENTAGE

Parentage	Number of Cases
American	22
Italian	22
Irish	13
Jewish	5
Negro	2
Syrian	1
Total	65

It was found that thirty-three of the cases (52.3 per cent) occurred singly without other members of the families having symptoms. On two occasions, groups of five persons were found to have trichinosis, and in one instance eight Italians became infected after eating fried pork sausages made at home.

An endeavor was made to determine the source of the infection in every case. In thirty cases (46.1 per cent) no definite relationship could be found between the disease and the food eaten. In only three instances was the meat eaten in a raw state without any preliminary cooking. In the remaining cases, it is evident that although the meat was cooked, it was not cooked thoroughly. Cooked pork sausage was the cause of the infection in fifteen cases, nine were due to boiled ham, six to cooked pork chops, one to fried ham, and one to cooked pork spare ribs. It is significant that several patients became infected after eating meat that had passed inspection by Federal meat inspectors.

An effort was made on several occasions to determine the incidence of infected pork on sale in Boston markets. This investigation was carried out in cooperation with Dr. Frederick J. Bailey, Deputy Health Commissioner of Boston. Small specimens of raw pork and pork products were obtained from several local markets. These were digested in artificial gastric juice and a search was made for larvae in the sediment. Trichinae were not found in any of the samples of pork examined.

Our observations indicate that the mortality rate of trichinosis in Boston is low, with only one death occurring in sixty five cases. The incidence of the disease appears about equally divided between those of American and of foreign parentage and not limited to those of low intellectual and social status. A majority of cases occurred in patients who had consumed cooked meat, and meat that had passed the inspection of Federal inspectors. From these facts, one might conclude that although the incidence of trichinosis is high, it is not a serious disease, and a suitable motto for its prevention would be, "Let the buyer beware and cook his pork thoroughly." But any clinician of experience knows that trichinosis may be a serious disease, leaving a patient prostrated for weeks. As for controlling the disease, it is well to consider some of the attempts that have been made.

Our knowledge concerning the parasite *Trichinella spiralis*, is about one hundred years old. Richard Owen⁸ is usually credited with its discovery in 1835. However, James Paget while still a medical student at St. Bartholomew's Hospital, made careful sketches and dissections of the parasite⁹ and called Owen's attention to his findings. These findings of Paget and Owen remained only of scientific interest until the brilliant work of the German pathologists, Virchow¹¹, Leuckart¹², and Zenker¹³ about 1860, emphasized their pathological significance. In the years from 1860 to 1866, the people of Prussia and Saxony were almost in a state of panic because of fear of the disease.¹⁴ A few years later the German Government instituted the method of examining microscopically the muscles of hogs killed for human consumption. This measure of prophylaxis against human trichinosis is still continued in Germany. After the system had been in use for several years at a considerable expense, it was found that the incidence of the disease had not been reduced according to expectations. The importation of unexamined American pork was blamed for its failure, and the importation of American pork to Germany was promptly prohibited. This materially affected the packing industry of our country, and in 1898 the United States Government sent Dr. C. W. Stiles to Germany to ascertain the value of microscopic examination of pork. His conclusions¹⁵ after two years' observation showed that out of 6,329 cases of trichinosis occurring in Germany between 1881 and 1898, 3,388 cases with 132 deaths appeared to have been due to faults of the method of German inspection. Furthermore, such a system gave a false sense of security, and pork was eaten raw. It is interesting as Stiles pointed out, that for Prussia alone the trichina inspection force in 1895 was almost as large as the entire regular army of the United States (27,089), and during the years of 1892 to 1895 the number of Prussian

trichina inspectors was greater than the number of enlisted men then authorized by law for the United States army. He estimated that the trichina inspection for Germany would cost \$500,000 to \$1,000,000 more than the entire annual appropriation for the United States Department of Agriculture for that year. The United States Government inaugurated a similar system in pork for foreign export in order to regain the market, but discontinued it in 1906 because of the excessive cost and its relative inefficiency.

It is assumed now as a governing principle in the United States, that the consumer is himself responsible for the proper preparation of fresh pork and pork products that are usually cooked before eating. The packer is, however, under obligation to make sure that pork products to be sold as cooked products are properly cooked or, if of a kind customarily eaten without cooking, to make sure that the products are free from viable trichinae.¹⁶

In 1914, Ransom¹⁷ showed that encysted larvae of *Trichinella spiralis* are destroyed by cold. As a result of these and further studies by Ransom and his co-workers¹⁷ all pork products of kinds customarily eaten without cooking which are prepared in establishments operating under Federal supervision are specially processed to destroy trichinae and are thereby rendered safe without cooking by the consumer. The methods of processing include cooking, refrigeration and special curing. Because of the exactitude required in these processes, they can be carried out effectively only in establishments under Federal supervision. Methods of preparing pork other than cooking are not readily applicable in the home. Therefore, the only safe rule in preparing pork purchased on the market not intended to be eaten without cooking is to cook it thoroughly.

One is frequently asked whether the ingestion of pork is the sole cause of trichinosis in humans. As far as we know, the eating of improperly prepared pork is the usual source of trichinosis in human cases although severe and fatal cases from the consumption of bear meat have occurred recently in California.¹⁸

It is the current conception that one of the chief methods of infection in swine is the eating of trichinosis rats which are alleged to be numerous where hogs feed upon garbage and offal. While it is known that swine readily eat dead rats thrown to them, our own observations made at both large and small piggeries have led us to question the generally accepted idea of the importance of rats as reservoirs of infection for swine. Never did we note any close association between swine and rats, even at feeding times. Garbage delivered to the piggeries was usually fed within a few hours to the pigs in their pens, runs and pastures. Rats were seen to feed only from temporary storage bins

or barrels or from the pig troughs after the hogs had left. At the time of slaughter in those piggeries in which the offal was fed back to hogs, this was immediately and completely devoured by the latter and at no time were rats seen attempting to approach it. It appears that the infection in swine may be chiefly of porcine origin (uncooked pork scraps and offal) and that the infection in rats may also be of porcine origin and transmitted through cannibalistic habits, but that the infection in the rat is seldom transmitted to the pig.

A survey (made by D. L. A.) for helminths in rats caught at piggeries and from the market districts, along the water front and at a large packing establishment in Boston supports this view. A total of two hundred and eighty rats was examined for helminths in this survey. Particular attention was given to the incidence of *Trichinella spiralis*. One hundred and ninety-three rats were trapped at four large piggeries located approximately twenty miles from Boston. Seventeen rats were caught at a packing house in Greater Boston and seventy were trapped in the market district and along the water front of Boston proper. Of the one hundred and ninety-three rats from the piggeries, only two were found trichinous, whereas nine or approximately 12 per cent of those from the market district and water front, and five or 42 per cent of the packing house rats were similarly infected. It is evident, therefore, that rats at these piggeries are not an important source of infection for the pigs.

Examinations of pigs for trichinosis were made at two piggeries. At one the food consisted largely of garbage collected from the residential districts of the town and, at times of slaughter, offal was fed to the remainder of the animals. Twelve young pigs which were to be slaughtered on the following day were given a skin test for trichinosis. All were negative by this test. At slaughter the diaphragms were obtained and examined after artificial peptic digestion. None were found trichinous. The second piggery was selected because three cases of trichinosis in man were known to have originated from it. Two large hogs which were to be slaughtered within the next few days and seven younger pigs, chosen at random as they fed upon garbage, were skin tested for trichinosis. One of these younger pigs developed a positive reaction while the tests on the others were negative. A precipitin test of the blood serum of this pig was likewise positive and the parasite was later demonstrated in the muscles. At this piggery the garbage was collected principally from small meat markets of the nearby city. A casual examination of the garbage held temporarily in barrels revealed pork scraps including a large piece of raw pork and several pieces of raw skin. It was evident that trichinosis in

this piggery originated directly from garbage.

These observations have, therefore, led us to believe that trichinosis in pigs (at least in this locality) is usually the result of their ingesting trichinous pork either in garbage or in the offal at times of slaughter and that the infection in rats, although relatively rare at the piggeries, has its origin in trichinous pork scraps, and may be transmitted from rat to rat through cannibalistic habits but that its return to swine through rats seldom occurs.

A review of the cases of trichinosis we have encountered within the past five years in eastern Massachusetts shows that the majority originated from locally raised and slaughtered hogs. As a specific example, during February of this year, twelve cases of the disease developed in a single family in consequence of eating pork from a hog to which the family had fed garbage collected in the town (not included in this series).

Inasmuch as trichinosis in swine in this region appears to have its source in garbage and offal it would be advisable to encourage the feeding of cooked garbage and cooked offal, particularly where garbage is collected from market districts and known to contain raw meat scraps.

Although our one absolute protection against trichinosis is by thorough cooking of pork, the necessity of thoroughly cooking all pork is not generally understood. To many the stamp "U S Inspected and Passed" is a guarantee that that piece of pork is free from trichinae and can be used without fear. It is not a lay conception alone but one that has been held correct by authorities on foods and sanitation, and so stated in textbooks on Hygiene and General Science now used extensively in our High Schools.

As stated by Riley and Scheffley: "It is evident that there is still abundant need for educating the public regarding the source of trichinosis and the simple means of protection that may be taken against the infection." It would seem that one of the most effective means of bringing this information to the public is through the school.

It is possible that at some future day trichinous hogs may be eliminated from the market by means of the serologic tests, now valuable aids in diagnosing the infection in man. The observations made by Augustine and Theiler¹ have shown that these are more accurate than muscle examination. No false positive skin reactions were encountered in swine in Massachusetts, even when concentrated dilutions of the antigen were used, but under tropical conditions, in the Panama Canal Zone and Colombia, South America, typical positive reactions were frequently encountered in non-trichinous hogs when concentrated dilutions of the antigen were used. High dilutions which were still effective in producing a typical reaction in trichinous hogs failed to produce a reaction in hogs sensitive

to the concentrated dilutions. The tests appear specific but further studies are necessary before their practical application can be determined.

For the present, the control of trichinosis obviously rests with the housekeeper, which means that all pork should be cooked thoroughly before it is eaten.

TRICHINIASIS AMONG JEWS

BY HYMAN MORRISON, M.D.*

TRICHINIASIS is recorded as the diagnosis in seven cases at the Beth Israel Hospital in the past four years four of the patients being Jews. This disease is not rare even under modern food control, but its occurrence among Jews is noteworthy and it indicates a change in an age-long dietary tradition. The pig has always been an unclean feeder and it is fair to assume that bitter experience was the basis for the specific injunction in the Mosaic code against the use of swine as food. Certainly there was no trichiniasis among Jews so long as they abstained from eating pork. With increasing lapse of dietary observance however, we must learn to consider this disease in differential diagnosis even among Jews.

The four cases mentioned above are reported here with a view of emphasizing two points. First and chiefly, the occurrence of this disease among Jews, and secondly, the importance of bearing in mind this disease when confronted with cases of fever of apparently unexplained origin.

CASE 1 A traveling salesman of forty came to our attention after he had been ill with fever for about three and a half weeks. His only complaint was dull headache and malaise. At the beginning of his illness a swelling about the eyes had been noted. Examination on the day before he was sent to the hospital revealed no apparent explanation for the fever but a stained smear of his blood showed an eosinophilia of twenty-five per cent. This was corroborated on his admission to the hospital and a routine investigation for fever of unknown origin brought out no other findings. A biopsy from the deltoid and soleus muscles disclosed encysted trichina embryos. Questioning as to his diet disclosed that in his travels he had eaten various pork prod-

ucts. The temperature became normal at the end of the fourth week of his illness and he has been well since.

CASE 2 A man of forty-two was admitted to the hospital with a story of heartburn and sharp burning pain in the epigastrium for three weeks. On admission he was found to have fever but this came down to normal four days later. Because a complete routine examination yielded no other data except an eosinophilic count ranging between twenty-nine and sixty-one per cent he was questioned as to his diet, and the fact was brought out that he had eaten pork three weeks previously followed for several days by diarrhea and puffiness of the eyelids to which he paid no attention. A biopsy revealed encysted trichina embryos.

CASES 3 and 4 Husband and wife both twenty-two years old. The wife was sent to the hospital with a provisional diagnosis of acute appendicitis. She had been ill for about a week with malaise and abdominal colic, at first localized in the right lower quadrant but subsequently diffuse. A routine blood examination showed an eosinophilia of sixty-eight per cent and subsequently biopsy revealed encysted larvae of trichina. Her husband came in several days later. His story was that a week previously he became ill with fever, malaise and abdominal distress and that four days later his eyelids became puffy and on the night before admission he had generalized muscular pain and soreness. At the hospital his eyelids were still puffy he had fever and his eosinophilic count was fifteen to forty-three per cent. The history now brought out that both he and his wife had eaten pork a few days before the onset of their illness. His temperature subsided four days after he entered the hospital.

Of the four patients only one presented the classical picture of trichiniasis when first observed at the hospital. This was the last case mentioned. The diagnosis in his case was simple because it had already been made in the case of his wife whose symptoms were chiefly abdominal pain. After the finding of eosinophilia by routine examination muscle biopsy

Morrison, Hyman—Professor in Clinical Medicine Tufts College Medical School. For record and address of author see This Week's Issue page 544.

cleared up the diagnosis. The first case was puzzling because he showed fever of over three weeks' duration without any explanation, and in this case, also, a routine blood smear examination gave the clue.

If the possibility of this disease is borne in mind, the diagnosis should not offer any difficulty. Remittent fever with muscle pain and edema localized around the eyes should at once prompt examination of the blood for eosinophilia and a searching inquiry for a history of the ingestion of pork. Finding of encysted larvae through muscle biopsy or the skin or precipitin tests makes the diagnosis absolute. If the patient is seen after the edema has disappeared, or if the edema is so slight as to be overlooked, or if the muscle pain is slight or limited to special muscle groups, then fever alone is the

dominant feature of the disease and the diagnosis may be baffling if the blood is not examined in a routine way. This accounts for the many failures in the diagnosis of such cases until the patients are taken to a hospital where routine blood examination gives the necessary clue.

SUMMARY

1 Four cases of trichiniasis among Jews, out of a total of seven, at the Beth Israel Hospital are cited briefly.

2 The diagnosis in all of them was obscure until a high eosinophile count gave the clue.

3 Because of the change in dietary habit, a diagnosis of trichiniasis should be borne in mind in cases of fever of obscure origin even among Jews.

THE ENERGY REQUIREMENT IN STRENUOUS MUSCULAR EXERCISE*

BY H. T. EDWARDS, A. A.,† A. THORNDIKE, JR., M. D.,† AND D. B. DILL, PH. D.†

STUDENTS of physiology are familiar with the report of Woods and Mansfield¹, that Maine lumbermen have an energy exchange of about 8,000 cals per day. Workmen are rarely called upon for such a high level of sustained effort. However, strenuous muscular exercise requires increased metabolism over certain definite periods of time. It is of interest to determine in this day of organized amateur athletics the energy requirement of sustained effort in such a sport as American football. In the last edition of Bainbridge², the statement was made that football players lose weight on a diet of less than 7,500 cals. We now have to report that measurements made during the past two years on Harvard football players show that on 5,600 cals body weight is maintained.

The menu at the Harvard training table is arranged by a trained dietitian under the supervision of one of the authors (A. T.). A varied diet unlimited in amount is provided. Lunch and dinner from Monday to Saturday noon are served.

Eight players were observed during three periods of several days each, one period in 1933 and two in 1934. Each item of food placed on the table was accurately weighed, and food residues were all collected and weighed. Weights of protein, fat and carbohydrate were calculated from standard tables^{3, 4}.

During the season of 1933 accurate estimates were made for lunch and dinner only, but in

1934 breakfasts also were served at the training table for six consecutive days. The average breakfast eaten during this period is shown in table 1 together with the estimated calories

TABLE 1

FOOD INTAKE AT BREAKFAST AND BETWEEN MEALS

During six days of the 1934 periods eight men ate breakfast at the training table and reported all food eaten between meals. The caloric value of extras is small and even if in error by 50 per cent the total will be not greatly in error.

		Carbohydrates	Proteins	Fats	Total
Breakfasts	Cals	699	122	582	1403
	%	50	9	41	
Extras	Cals	131	36	121	288
	%	46	12	42	

intake between meals. The estimated *extra* calories were consistent from day to day and amounted only to about five per cent of the total food intake.

We thus obtained, by addition of the average breakfast and estimated extras to the measured lunches and dinners for the three periods, the total caloric intakes shown in table 2. The weights of the players were observed daily as shown in table 3. There were the usual day-to-day fluctuations, but no significant net change in the average weight from Monday through Friday. It may be concluded, therefore, that these players had an average energy requirement of about 5,600 cals during the periods studied. The average for the week may be slightly less because the players eat lightly on Saturday before the game (table 2) and are cautioned to eat a light dinner after the game.

*From the Fatigue Laboratory, Morgan Hall and the Department of Hygiene, Harvard University, Cambridge, Mass.

†Edwards, H. T.—Assistant, Fatigue Laboratory, Harvard University Medical School, Boston. Thorndike, A. Jr.—Surgeon, Department of Hygiene, Harvard University Medical School. Dill, D. B.—Assistant Professor of Biological Chemistry, Harvard University Medical School. For records and addresses of authors see "This Week's Issue" page 544.

From verbal reports, Sunday appears to be a feast day and may in a large measure offset the low intake of Saturday.

An estimate may be made of the proportion of the total energy required for football. These

Saturday game average about two hours each, it follows that the increased requirement attributable directly and indirectly to an hour of football playing is one half this quantity, or 1,250 cal. If this increased metabolism were

sixteen men had a mean height of 184 cm. and a weight of 83 kg which corresponds, according to accepted standards, to a basal metabolism of 80 to 84 cal. per hour, in other words to about 2,000 cal. per day. According to Rubner's figures* such an individual in light activity would require about 2,800 cal. per day. The

difference attributable, directly and indirectly, to football is 5,600 — 2,800 = 2,800 cal. Subtracting ten per cent (300 cal.) for loss through the urine and feces there remain roughly 2,500 cal. attributable directly and indirectly to football playing. Since the daily practice and the

limited to the period of play, football playing would involve an increase in the metabolic rate of about fifteen times normal. But the data collected by Lusk* indicate that the trained athlete is capable of increasing his resting metabolic rate only about ten fold in any sustained effort. While an increase of fifteen times resting metabolism may occur in a marathon race during a period of two and one-half hours, such an effort could hardly be made six days a week. We accordingly assume a metabolism during play of 800 cal. per hour.

Since the metabolism of Rubner's student during his working hours is approximately 135 cal. per hour, this represents an increased metabolism of 800 — 135 or 665 cal. per hour, i.e., $2 \times 665 = 1,330$ cal. per day which is directly attributable to playing football. But the increased metabolism directly and indirectly attributable to playing football is 2,500 cal. per day. This amount less 1,330 cal. directly attributable to football gives 1,170 or in round numbers 1,200 cal. increased metabolism per day indirectly attributable to football.

Accordingly, a large part (roughly one-half) of the increased metabolism attributable to football occurs after the game is over. Only a

small fraction of this can be considered as oxygen debt in the sense used by Hill and his associates⁷ When players leave the field, their blood lactate may be as high as 100 mg per 100 cc but according to the calculations of Margaria, Edwards, and Dill⁸ this implies an oxygen debt of only eight or ten liters, equivalent to about four per cent of the 1,200-cals excess. However, no matter what name is given to this excess oxygen consumption, it must be considered a consequence of strenuous activity. Benedict and Carpenter⁹ studied this phenomenon. A summary of their results is shown in table 4.

TABLE 4

A L L	78.3	—	83.7	97.9

*All work ceased at least 7 hours before metabolism measurements began except in the case of very severe work in which work ceased but 1 hour before.

The same phenomenon has been studied recently by Herxheimer, Wissing and Wolff¹⁰. They find that even forty-eight to seventy-two hours after severe work the metabolism may be ten per cent above normal. While they concluded that this increase is a consequence primarily of severe work, we find that even when the work is only seven times the resting metabolic rate, with no increase in lactic acid, there is a considerable increase in resting metabolism¹¹. Apparently,

the increase depends on quantity of work, i.e., it is a function not only of intensity of work, but of its duration also.

Table 5 contains measurements of the B.M.R. of three members of the Harvard team. They were studied shortly after being awakened on each of seven successive mornings following a game, and subsequently on the morning after the weekly game, and finally some weeks after the season was over. Then metabolism in this final study was high enough to suggest that in the above computations a value slightly higher than Rubner's⁵ should have been employed. It is clear, however, that even fifteen hours after a game or a strenuous practice, as notably after the Thursday practice, the metabolic rate is in general distinctly elevated. Observations on subjects in this laboratory indicate that while lactic acid, alkaline reserve and other properties of the blood return to the resting level promptly, the metabolism after strenuous activity returns to normal asymptotically and slowly, the fact that it may be twenty-five per cent above normal after fifteen hours' recovery gives some clue to the elevation in earlier stages of recovery.

In lacrosse, a game similar in intensity and duration to American football, the metabolism was twenty-three per cent above its minimal value after thirteen hours and eight per cent after thirty-one hours.

The significance of these facts is twofold. The modern program of physical activity for the college student entails for many men, besides those on football teams, an unusually large caloric requirement. This means that any dietary régime based on the assumption that the college student is a sedentary person or even engaged in moderate activity is apt to be erroneous. Adequate allowance must be made for the wide range in requirement. The average requirement is meaningless, if it is supplied arbitrarily, the sedentary student will be surfeited.

*Strenuous practice preceding afternoon

and the student engaged in strenuous sport will go hungry.

The other point worthy of emphasis is that the increase in resting metabolism should be taken into account in calculating the dietary requirement of a given activity. It is a common practice to determine the oxygen intake during activity and neglect the fact that hours may elapse before metabolism has returned to normal. If this were applied to football players, we might estimate that the twenty-four hour requirement is $2,800 + (2 \times 665)$ or 4,130 cal. Our results indicate that such a calculation would be in error by about 1,500 cal., since we have presented sufficient proof to establish 5,600 as the average caloric requirement of football players.

CONCLUSION

From this study of the diets, weights and metabolic rates of two groups of football players we conclude that

- 1 The average energy requirement is 5,600 cal. per day.
- 2 Approximately twelve per cent of this requirement is provided by protein, forty-four per cent by carbohydrates and forty-four per cent by fat.
- 3 On the assumption of a metabolic rate of

ten times the normal B.M.R., fifty per cent of the energy requirement of football playing remains to be accounted for after the game.

4 After physical activity has ceased the return to normal metabolism is slow and fifteen hours after activity the B.M.R. may be plus twenty-five.

5 This increased resting metabolism must be provided for.

MASSACHUSETTS DEPARTMENT OF HEALTH WORCESTER CANCER CLINIC

The Worcester Cancer Clinic of the Massachusetts Department of Health has been reorganized and its work concentrated at Memorial Hospital where excellent accommodations have been placed at its disposal by the trustees and Superintendent Stone.

Its staff has been augmented by representative specialists from all the hospitals. At least three specialists will be in attendance at each session of the clinic in order that patients referred may have the benefit of group diagnosis as prescribed by the American College of Surgeons. This is a purely diagnostic clinic. Each case will be sent back to the referring doctor or hospital with a full report as to diagnosis and treatment advised.

There are no charges for this service and it is open to all classes provided applicants are accompanied by their physicians or bring referring letters from their physicians, or from hospitals or welfare organizations.

The clinics are held each Wednesday at 11 A.M. in the Out Patient building at Memorial Hospital, Belmont Street, Worcester.

This clinic does not supersede or interfere in any way with the treatment clinics maintained by the hospitals and conducted under their rules but supplements them by group diagnosis and social service.

It is hoped that physicians will avail themselves of the opportunity to observe cancer cases by being present at the clinics especially when presenting patients of their own.

TRACY B MALLORY, M.D., *Editor*

CASE 21371

PRESENTATION OF CASE

A thirty-three year old American taxi driver entered complaining of pain in the left lower quadrant

Approximately two months before entry the patient first developed a dull ache in the left lower quadrant, appearing usually upon standing and walking and relieved by lying down. The pain persisted and was relieved only when he went to bed. Upon defecation the pain radiated sharply around to the back and occasionally to the right. There was no relation of the pain to meals. About one week after the onset he noticed that his left testis had gradually become swollen and was often painful, especially when high in the scrotum. During the past month he had slight frequency during the day and nocturia. There was no dysuria or hematuria. His bowels were regular and there was no diarrhea. During the past month he noticed that the shape of his feces had been flatter. There had not been any tarry or clay colored stools and once after taking a cathartic he passed whole blood for one day. He attributed this blood to piles which he had had for at least six years. Occasionally he had a similar pain in the right lower quadrant, but this was mild and only transient. During this illness he had lost a good deal of his energy and ambition. He had lost about twelve pounds in weight. Two weeks before entry he noticed a small hard lump in the left lower quadrant. Recently it was pointed out to him at a clinic that this mass had grown in size.

His family history is non-contributory.

He had a Neisserian infection ten years before entry which was treated for about three months. Associated with this infection he had venereal warts. Three years later he had a second Neisserian infection which was followed by a chronic prostatitis. This was treated routinely twice a week for about six months.

Physical examination showed a well-developed, muscular man. The heart and lungs were negative. Just to the left of the midline in the lower quadrant was a large non-movable nodular mass, approximately 10 by 6 by 4 centime-

ters. The prostate was boggy. There was a left hydrocele.

The temperature was 99°, the pulse 78. The respirations were 20. Blood pressure was 114/74.

Laboratory examination of the urine was negative. The blood showed a red cell count of 5,510,000, with a hemoglobin of 80 per cent. The white cell count was 9,300, 76 per cent polymorphonuclears. The stools were soft, firm, blackish brown, and showed a 2 plus guaiac.

X-ray of the chest showed slight tenting of the left diaphragm in the region of the heart. A flat abdominal plate showed normal kidneys and no evidence of urinary calculi. A barium enema stopped abruptly after it had filled the rectum. The colon could not be filled beyond this point. It could not be determined whether or not the overlying soft tissue mass was intrinsic or extrinsic. An intravenous pyelogram was negative.

On the eighth day an exploratory laparotomy was performed.

He developed a few râles in the right base postoperatively. These, however, cleared up and he was discharged two weeks after operation.

He returned six days later because of marked cramps in the lower abdomen with distention. An ileostomy was performed under local anesthesia. Following operation he received fluids intravenously and was kept comfortable with opiates. He gradually went downhill and died on the eleventh postoperative day.

DIFFERENTIAL DIAGNOSIS

DR GRANTLEY W TAYLOR. Pain in the left lower quadrant is rather apt to be more obscure and due to more diverse causes than pain in the right lower quadrant. The history brings out one brief relationship to the gastrointestinal tract, namely, that on defecation he had radiation of pain to the back, and a definite implication of the genitourinary tract in that his testis was swollen and painful and he had slight frequency and nocturia. We want more data before we can decide which one of these tracts is primarily involved in the process. The character of bleeding from the rectum must be carefully gone into as one takes a history. I think in regard to a single bleeding episode one is perhaps justified in attaching less significance to it than if it were the usual thing. We might find that it is present especially after vigorous catharsis, sometimes in relation to trauma and sometimes in relation to piles. This bleeding episode may have no significance in the clinical picture as you see it now.

The loss in weight and energy is the first indication that this is more than a purely local process. It is severe enough to involve and affect the entire individual to some extent. The

presence of a mass is the first indication we have that there is any physical abnormality except for a swelling of his testicle which was referred to farther back.

We have a very definite past history episode which might conceivably enter into the picture along with the swollen testicle, pain, frequency etc. It is worthwhile to pause for a minute and wonder if the whole picture, including the mass, could be accounted for by some complication of Neisserian infection and chronic prostatitis. Prostatitis due to Neisserian infection is very common but the number of times we see an adominal mass associated with it is so infrequent as to be a rarity. I have never heard of it.

The history states that the mass has grown very rapidly to a rather large size. A mass of this sort you would like to be able to feel for yourself to know if it had been entirely discrete from true pelvis or whether it was barely sticking out that much from below. Whether a mass of that sort is fluctuant or hard is of considerable significance in the diagnosis. We know that it is fixed and nodular. If you had a suppurative process or an infectious process reaching that size in that space of time it seems to me it would be reasonable to look for some evidence of fluctuation. You might also find some evidence of fluctuation in a neoplastic mass that had grown to that size.

Those evidences which we have had pointing toward the urological tract, to wit the painful testicle which was swollen, the hydrocele and the slight change in urinary habits, do not necessarily mean that the primary process originated in that tract. You can have disturbances of the urinary tract of that sort from extrinsic tumors which impinge on the nerve or blood supply or lymphatic return from the region of the testicle. Hydrocele is very commonly associated with inflammatory or neoplastic processes in or about the inguinal region or in the pelvis in deep relationship to the drainage from these areas, so although the symptoms require that we investigate with some care, it does not necessarily mean we will find primary trouble in that region. The temperature of 99°, the normal pulse and the white count of 9300 with 76 per cent polymorphonuclears are the only data which will bear on the presence or absence of a primary inflammatory process. It seems to me there is no very good ground for suspecting sepsis. It does not mean, however, that it cannot be present. A chronic inflammatory process occasionally gives rise to very little in the way of reaction in the chart, especially long standing tuberculosis or long standing abscess of any cause. On the other hand we have the patient's story to the effect that this has been a rapid development, and it seems to me any inflammatory process as rapid as that would still be giving rise to considerable variations in the

chart and influencing the leucocyte count more than it is. The possible exception might be tuberculosis.

The stools were soft, firm, blackish brown and showed a two plus guaiac which would be in keeping with a lesion in the gastrointestinal tract, but on one observation a positive guaiac is not very significant, especially if the patient is not on a restricted diet. It would be consistent with the history of bleeding. We should like to know whether there were hemorrhoids present and also some statement as to the character of the rectum in so far as it was subjected to examination by the finger. We will assume that it was negative or they would have commented on it. In connection with the possibility of chronic piles or bleeding of any significance in the gastrointestinal tract, we must consider the high red count which certainly means the patient has not had chronic blood loss or any acute blood loss within recent times.

It is hard to know why a chest x ray was taken unless the condition was considered tuberculous and they were looking for confirmation of tuberculosis elsewhere in the body. Tenting of the diaphragm does not mean very much to me.

X RAY INTERPRETATION

DR GEORGE W HOLMES. As Dr Taylor has suggested, this is the so called tenting of the diaphragm. Sometimes, at least, these changes are due to adhesions between the diaphragm and pleura at the base of the lung, they are sometimes due to localized areas of atelectasis in the lung, sometimes unexplained. I do not think they are of any clinical importance in this case. His lungs are unusually clear. As Dr Taylor suggested, it is possible that the film was taken to rule out tuberculosis but I think it more likely that the observer had in mind the possibility of malignancy in the lung and wanted to be sure there were no metastases in the lung or mediastinum. The heart is normal in size and shape and there is no evidence of changes in the aorta. You can see the fairly well filled ureters and a small amount of dye in the bladder. This shadow is well outside the ureter and is probably a calcified gland. It is on the right side. The tumor mass that was felt was on the left side. I presume that the patient was unable to retain the enema and that the obstruction was so low that the enema was expelled before the examiner had an opportunity to take a film.

DIFFERENTIAL DIAGNOSIS CONTINUED

DR TAYLOR. This x ray information gives us definitely more data and tends to exempt the primary tract as a primary focus for the process. It would be a very large tumor indeed which would give rise to obstruction high in the rectum and at the same time be felt above Poupart's

ligament, and there should be some connection between the two. We have definite stoppage of the colon between the rectum and the sigmoid. The x-ray could not determine whether it was intrinsic or extrinsic. The x-ray also points out that we are not dealing with a bone tumor in that region.

We are left with a tumor in the lower abdomen and a lesion that has caused some loss of weight, strength, etc., and it seems to me we have to make up our minds what it is. It is hard to know without further data. We should like certainly to have a proctoscopic examination. It seems to me that at proctoscopy one would have been confronted with a wall of perfectly normal, smooth, rectal mucosa, with some trouble in deciding whether the bowel lumen passed behind that wall, and whether right or left or anterior to it. Certainly there is nothing characteristic of primary new growth in the rectum or rectosigmoid region, in spite of the few things pointing in that direction. Let us consider again the possibility of an inflammatory process. Diverticulitis and that sort of thing we cannot rule in or out. Certainly the history does not disclose anything to make us think that that is the right diagnosis. Primary neoplasm, retroperitoneal sarcoma, is a kind of catch all. A tremendous number of tumors appear in that region—lymphomas, chordomas or sarcomas. We see a certain number of metastatic tumors in the pelvis from primary foci which are silent but which may give infiltration of the lymph nodes or direct tumor extension. It is possible that something of the sort is responsible for this picture. It seems to me the significant thing is the very rapid growth that the lesion has had and the relative freedom from localizing symptoms, so I should say retroperitoneal malignant tumor, possibly lymphoma, was the best bet.

The patient was explored on the eighth day. I do not know what was done. It would seem as long as there was obstruction of the colon by x-ray it might have been considered desirable to do a colostomy at that time. Certainly exploration would shed more light, but on exploration I suspect a definite diagnosis could not be arrived at unless a biopsy was removed. Undoubtedly any abdominal organs passing into the pelvis went into a dense matted mass the nature of which was obscure to the surgeon. He might or might not have removed a specimen for pathologic examination and closed the abdomen.

The ileostomy was done presumably as an emergency measure. It is interesting that his obstruction required an ileostomy rather than a colostomy. You would suppose that obstruction would be at the place pointed out by x-ray. But under novocain you take what you can and put a catheter in.

As regards the immediate cause of death in this case, we do not know but it seems unlikely that the tumor has progressed so rapidly as to cause demise. Whether he had peritonitis, whether he had ileus or dehydration, you cannot tell. I should feel that if I saw this case clinically I would not be any clearer as to diagnosis until I had seen the autopsy. I should place my bet on malignancy in the pelvis, rapidly growing, and await the pathologist to tell us the findings.

DR TRAUB B MALLORY Dr Leland, you saw the patient on the wards. Have you anything to add?

DR GEORGE A LELAND, JR I saw this patient prior to both of his operations but did not operate upon him. Anybody seeing a patient in vivo certainly has an advantage over the man who tries to make the diagnosis from a sheet of paper. As one looked at this man, the likelihood of inflammatory disease did not strike one as being very probable. The mass was hard, quite completely fixed, and in a very bizarre situation. Tests were undertaken as indicated to determine as far as possible its origin, whether the urological system or the gastrointestinal tract. It was felt that any preoperative diagnosis was chiefly of academic interest because it was quite apparent that it must be some malignant condition. Exploration was undertaken with the hope of ascertaining whether or not the malignant condition might be amenable to palliation from x-ray therapy. In the Outpatient Department a diagnosis of retroperitoneal lymphosarcoma had been made. Further studies in the ward did not advance us any farther and he was explored with that preoperative diagnosis.

CLINICAL DIAGNOSES

Preoperative Retroperitoneal sarcoma
Postoperative Carcinomatosis

DR GRANTLEY W TAYLOR'S DIAGNOSES

Malignant tumor of pelvis
Retroperitoneal sarcoma?

ANATOMIO DIAGNOSES

Colloid adenocarcinoma of sigmoid with multiple peritoneal metastases
Pulmonary edema, bilateral
Esophagitis, acute
Hydrothorax, bilateral
Cholesterosis of gall bladder
Multiple ulcers of small intestine
Septicemia, hemolytic streptococcus

PATHOLOGIC DISCUSSION

DR MALLORY Dr Rogers did the exploration and found the pelvis and lower abdomen completely filled with an irregular mass of malignant tissue apparently arising from the left

posterior wall but he was unable to localize it any more accurately than that. He was still completely in the dark as to the primary source of the tumor. A piece of tumor was excised and showed colloid adenocarcinoma.

His second operation, of course, was for intestinal obstruction and although the patient died a very short time after that, within the short interval between the time of the first operation and death this malignancy had spread throughout the abdominal cavity so that the entire omentum and almost every structure in the cavity was a mass of gelatinous colloid material. The rate at which colloid carcinomas sometimes extend once they begin to grow freely in the abdominal cavity is almost incredible. Following the ileostomy a localized peritonitis had developed and I think was probably the immediate cause of death.

DR. TAYLOR: Did you find the source of the carcinoma?

DR. MALLORY: It was at the rectosigmoid junction, a very small portion only lying within the lumen of the bowel, not more than two centimeters in diameter. The vast majority of the tumor was lying almost free in the peritoneal cavity.

A PHYSICIAN: It was ulcerated and he was bleeding from it?

DR. MALLORY: Slightly, yes.

CASE 21372

PRESENTATION OF CASE

A fifty-one year old divorced Canadian practical nurse entered complaining of sore throat of two weeks' duration.

The patient had been working on a case doing twenty-four hour duty for five weeks. Two weeks before entry she developed a sore throat near the left tonsil. This was associated with pain on swallowing. A physician swabbed the throat with phenol and glycerin. She became very tired and the condition in her throat grew worse. On the fourth day she went to bed, where she stayed for two days. Two days later a physician incised her throat to allow for free drainage. During the week before admission she was very feverish and chilly although she had no definite chills. She developed a constant head ache and vomited once. The throat became very sore and she was able to take only liquid foods. Six days before admission she applied a hot water bag to her neck which resulted in a slight burn. On the evening before entry she took six allonal tablets.

Her father died of Bright's disease. Her mother and seven siblings were living and well.

She was married at sixteen and divorced at twenty-one. She had one child who died at the age of six months. There were no miscarriages.

She had measles as a child and diphtheria at

the ages of twenty-five and twenty-eight. (sic) At the time of the birth of her child she developed peritonitis. For a period of fifteen years preceding the past fifteen years she had attacks of tonsillitis every spring. She had never had attacks similar to the present illness.

Physical examination showed a fairly well-developed and nourished woman apparently drugged but fairly well oriented. The skin was sallow. The cheeks were flushed. The pupils were contracted and reacted very slightly. Examination of the throat showed a large area of gray ulceration with a sharply demarcated non-inflammatory border over the left tonsil. Smaller and similar areas were present above the uvula and on the anterior pillar. The breath was foul. There were a few moist râles at both bases. The abdomen was slightly distended and tympanic.

The temperature was 101.2°, the pulse 100. The respirations were 22.

Examination of the urine showed a specific gravity of 1.016 to 1.020 with a slight trace of albumin and a brown test for sugar. The sediment was not remarkable. The blood showed a red cell count of 3,480,000 with a hemoglobin of 60 per cent, and a white cell count of 650. The smear showed 94 per cent lymphocytes and 6 per cent large mononuclears. There were no polymorphonuclears. The platelets were normal. Examination of the stools was negative. A smear of the left tonsillar region showed Vincent's spirochetes. The Hinton test was negative. The nonprotein nitrogen of the blood was 38 milligrams.

She was given intravenous glucose and several injections of pentnucleotide intramuscularly. Blood examinations on the second and third days showed white cell counts of 1,150 and 1,500 respectively. Both smears showed one hundred per cent lymphocytes. She failed very rapidly. The temperature rose steadily to 106°, she became irrational, developed an early cellulitis of the left arm, and died on the third day.

DIFFERENTIAL DIAGNOSIS

DR. F. DENNETTE ADAMS: The history in this case indicates that one is dealing with something more serious than ordinary sore throat. During the first few days there was apparently nothing to distinguish it from the usual case of acute tonsillitis and pharyngitis, but with this type of infection the patient should have been getting better, not progressively worse, at the end of a week. The record fails to indicate whether pus was obtained from incising the area. If we could be sure it was not, we would have an important diagnostic point. It is not uncommon in cases of agranulocytosis, even before the appearance of definite ulceration, for the throat to develop edema sufficient to be confused with the swelling of peritonsillar abscess.

The fact that the patient took six allonal tablets during the night before admission causes one to speculate as to whether she might not have had similar medication earlier in the disease. It is tempting to assume that being a nurse and consequently familiar with drugs, being tired and sick, she might well have tried to combat fatigue, insomnia and infection with this drug during the earlier stages. Allonal contains amidopyrin, which is considered by many to be a dangerous drug. It is generally agreed that in certain individuals who appear to have a particular susceptibility there is a relationship between its use and the development of agranulocytosis.

Diphtheria at twenty-five with a second attack at twenty-eight is quite possible, particularly in a nurse.

The areas of ulceration in the throat are consistent with agranulocytosis. The description does not suggest diphtheria, Vincent's angina is possible, but the patient was sicker than one would expect if only this disease were present. The râles in the chest could be simple congestion or the earliest sign of developing bronchopneumonia.

The blood count with practically total elimination of the granulocytic elements is typical of agranulocytosis. The presence of spirochetes of the Vincent type is not surprising. They are found in any type of ulcerative lesion in the mouth but not customarily in so great numbers as in the case of true Vincent's angina, where myriads are found in any smear, provided it is taken not from the surface slough but from the deeper and more active part of the lesion.

The blood culture is not reported. Septicemia might or might not be present.

The abscess on the arm is not localized in our summary. With no added information we might surmise that it came from glucose leaking into the tissues around the vein at the point of injection or from a hypodermic injection in a patient obviously lacking any resistance to infection. Failure to respond to nucleotide might be explainable on the basis of severity of the disease and the late stage at which it was administered, but opinion as to its efficacy in all cases, even if treated early, is not uniform.

The evidence in this case of acute sore throat with ulceration, marked prostration, and rapid downhill course, taken into consideration with the history of allonal ingestion, the physical findings and the blood count, is overwhelmingly in favor of agranulocytosis. Septicemia or bronchopneumonia, or both, may be present. The relationship between the disease and the use of drug containing amidopyrin cannot be stated definitely, but there is evidence sufficient to make one suspect that the drug may have been an important etiologic factor.

A PHYSICIAN: Are you satisfied as to the throat cultures and examination?

DR. ADAMS: By that do you mean they should

have been studied for diphtheria? The type of lesion described is certainly not a typical picture of diphtheria. Cultures for diphtheria must have been taken. It is, I believe, a routine procedure on acute throat cases in this hospital.

A PHYSICIAN: What about blood stream infection? Is there a possibility of that?

DR. ADAMS: General septicemia? Most of these patients show no positive blood cultures but some do become positive in the late stages.

DR. TRACY B. MALLORY: A good many of them do, in my experience, though it is hard to say how large a proportion. Probably twenty-five per cent show positive cultures. Especially in the earlier cases reported several years ago there was a striking frequency of positive blood cultures with organisms ordinarily considered non-pathogenic, such as staphylococcus albus and bacillus pyocyaneus.

A PHYSICIAN: How often do you find it with Vincent's?

DR. MALLORY: A large proportion of the cases will show Vincent's organisms in the throat.

We never did get an accurate past history in this case and we do not know how long she had been taking allonal, but I should think the deduction reasonable that one who takes six pills must be familiar with the drug. I cannot imagine anybody swallowing that many who had never taken them before. Habituation to this particular group of drugs is an extraordinarily common thing in the nursing profession, also in the medical profession and the families of medical men. Dr. Hunter, who has just finished a very careful review of the literature on agranulocytosis, found, as other people have, that an overwhelming proportion, more than three fourths of the cases, have been in nurses, doctors and doctors' families. It is peculiarly a disease of the medical profession and closely related individuals. There is also a notable difference in the number of cases in different countries. Germany and America have provided the greatest number of cases, England and France, where coal tar drugs are less popular, many fewer.

CLINICAL DIAGNOSES

Agranulocytic angina
Aleukemic leukemia?
Septicemia

DR. F. DENNETTE ADAMS'S DIAGNOSES

Agranulocytosis
Septicemia, terminal?
Bronchopneumonia, terminal?

ANATOMIC DIAGNOSES

Agranulocytic angina.
Septicemia with lymphangitis of left arm
Ulcerative stomatitis
Esophagitis, acute

Bronchopneumonia, early
Endocarditis, acute, mitral
Hydropicardium
Arteriosclerosis Aortic and coronary, slight
Chronic salpingitis
Leiomyomata uteri

PATHOLOGIC DISCUSSION

DR. MALLORY The autopsy on this patient was fairly typical of this disease. There was a terminal pulmonary infection which showed histologically fibrin, serous exudate and red cells—everything characteristic of pneumonia except leukocytes. A rather unusual finding was an ulcer in the esophagus which was very peculiar in appearance. On its surface were a lot of bright yellow granules, one millimeter to two millimeters in size, which looked like colonies of staphylococcus aureus on a blood agar plate. That in fact was what they were. Each little granule was a colony of millions of bacteria around which there was no leucocytic response at all. They were growing exactly as they do on favorable culture media.

She had an ulcer in the stomach as well which was interesting histologically for, whereas the vast majority of stomach ulcers are entirely free from bacteria, this ulcer showed a thick layer of bacteria all the way around it.

A PHYSICIAN This was not a chronic ulcer?

DR. MALLORY No, a very acute one.

A PHYSICIAN Was it something that developed during the course of the disease?

DR. MALLORY We think so.

A PHYSICIAN Were these organisms spirochetes?

DR. MALLORY No.

The bone marrow in these people presents extremely variable pictures. There are three types that I have seen. You sometimes see people dying of an acute infection with a white cell count down to 1,000 or lower, few or no polymorphonuclears in the smear, and at autopsy you find a bone marrow that is totally lacking in granulocytes but with red cell formation going on in a normal fashion. Those cases have always had, in my experience, an infection, generally a septicemia, with an organism of high virulence, such as a hemolytic streptococcus.

Dr. Jackson rules that group out and says that they are not true agranulocytosis. The leukopenia is to be regarded as secondary to a toxemia. The more typical cases, where the lesions tend to remain superficial and the organisms are of only average or low virulence, in whom you can often get a history of several recurrences of the disease and in whom we so frequently in the last two years have obtained a history of the ingestion of amidopyrin, show quite a different picture. In them the bone marrow is swarming with immature stem cells and it would be a fairly easy thing to mistake the section for one of leukemia. In fact, I am very sure that has often been done in the past. This type of case Dr. Jackson likes to compare with the bone marrow picture in pernicious anemia where red cells are being formed in more than sufficient numbers but they are not being matured to the point where they can be delivered into circulation and be useful. In true agranulocytosis the white cells are not being matured, most of them remain as stem cells, a few become myelocytes, practically none differentiate to leukocytes.

In patients that have run a somewhat longer course—this woman was in the hospital three days and had been sick for nearly two weeks, so that as cases go we can say she had reached the chronic stage—one often finds the bone marrow loaded with plasma cells. They may be so numerous that the sections may raise a question of a diagnosis of multiple myeloma. Such a picture is rarely seen in cases dying within the first four or five days of the disease but becomes common in those lasting seven days or longer.

A PHYSICIAN What is the feeling here about the use of liver extract in treatment?

DR. MALLORY None of us here can see any logic in it.

A PHYSICIAN Why would not a transfusion have helped her?

DR. MALLORY The local experience here has been that transfusions do not help. We have seen a number of bad reactions and no good results. It has become a matter of policy not to use them. It is only fair to admit, however, that any one person can see only a small number of these cases and hence is hardly justified in coming to a dogmatic conclusion. That just happens to have been our experience here.

LEAD THERAPY OF CANCER

THE *New York Times*, under date of August 21, 1935, reports an attempt to revive the long-quiescent use of lead in the treatment of cancer. The paper was read by a group from the Mayo Clinic before the American Chemical Society. It is certainly unfair to say that the excellent facilities for publicity afforded by the presentation of a paper before such a gathering had anything to do with the choice of audience. But it is unfortunate to present material of interest to thousands of sufferers before a group which, by virtue of divergent interests and training, is incapable of thoroughly criticizing and evaluating it.

Whereas material of primarily chemical nature is properly treated before a group of chemists, a paper which apparently emphasizes chiefly the results of therapy, particularly in such a disease as cancer, seems definitely out of place. In this instance presentation before a group

interested and experienced in cancer treatment would be far more valuable.

As far as one can judge from the quotation in the newspaper seven cases of eighty-five, all inoperable, improved with lead treatment alone. The investigators do bring out the fact, established years ago, that unless lead therapy is pushed to the point of toxic symptoms, little in therapeutic results may be expected.

Following Blair Bell's initial announcement, some ten years ago, lead therapy was taken up in various centers and carefully scrutinized. Little value, however, has been derived from the use of this form of treatment in the past. When one considers the dangerous and painful effects of acute lead poisoning, considerable hesitancy is indicated before using such an uncertainly helpful and surely dangerous substance.

It is indeed to be regretted that such wide spread publicity has attended a report which encourages the wider use of lead compounds in cancer therapy. If and when details of the procedures of Osterberg, Borgen, and Horton are presented before medical groups or published in periodicals seen by physicians it may be possible to evaluate the importance of their contribution. We all hope they have made a step forward in the struggle against the disease. For the present, at least, the general reluctance to use lead compounds in treating cancer should continue.

THE INTERN AND INSURANCE

RECENT reports are to the effect that the Interstate Council of Greater New York has sought legislative action to provide for interns appropriate compensation and proper "insurance protection in case of mishap, disability or death suffered in line of duty." The movement has been characterized as an enlightened protest against the exploitation of the intern and is to be taken as another sign of the growing self-consciousness of this group of young physicians. The implication is that because they are hospital employees the cost of such insurance should be borne by the institution. Thus the burdens of the hospital administrator are becoming more onerous almost daily, but there is here a problem that deserves most careful and thorough study.

Again, the legal status of the activities of the intern is not always clear. Is he practicing medicine? Is he licensed so to do? Is he subject in every way to the provisions of the medical practice act? Is he responsible as any other physician in all civil matters involving his profession and in all the laws of the state pertaining to the practice of medicine, including malpractice?

That the intern is substantially practicing medicine is clear. Whether he does so in the legal sense is not always so clear. Physicians may and do delegate to nonlicensed persons certain tasks which otherwise the physicians themselves would perform. Which of these tasks are the practice of medicine? It is because there were delegated to interns many duties, performed in the absence of the registered physician and involving the assuming of certain responsibility by the intern, that it was thought best in Massachusetts to protect hospitals and medical staffs and interns by specific license of this third group.

The restrictions under the statute are as follows: "But such limited registration (as intern) shall entitle the said applicant to practice medicine only in the hospital or other institution designated on his certificate of limited registration, or outside such hospital or other institution for treatment, under the supervision of one of its medical officers who is a duly registered physician, or persons accepted by it as patients and in either case under the regulations established by such hospital or other institution."

Under the license he is subject to every provision of the medical practice act, and all the laws of the Commonwealth pertaining to the practice of medicine, including malpractice.

But he is an officer of the hospital and an employee and certain of his acts are in this capacity. For example, he does not need an individual narcotic permit if the hospital is duly registered under the narcotic regulations. As an officer of a charitable institution he is protected against certain claims by law. What protection has he if he is dealing with a patient who is not a charity patient?

His position differs, however, from that of the physician not an intern in that he is in part an agent and may be called upon to perform acts on which he is not competent to pass judgment medically. The visiting physician has left an order which he carries out to the best of his ability. Some sort of disaster occurs and suit is brought against him for malpractice.

Should the intern be protected by insurance? Should the hospital or the medical staff or the intern pay for such insurance? The answer will depend in part on the laws of the state. However, this should be kept in mind. Insurance against malpractice suits is one of the most certain ways to stimulate such suits. The purpose of these suits generally is to obtain a financial salve for a real or imaginary harmful result of the action of the agent. If the agent has no money, he cannot pay money and suit is not likely. If it is generally known that a wealthy insurance company is back of the intern a lawsuit may be an appealingly easy way to get some of the company's money. Certainly suits for malpractice have enormously increased

since insurance companies have entered the field in defending physicians and paying damages.

The value of such an organization as has been set up in New York will depend on what it does. It is capable of much good; it is capable of much harm. *Pessima corruptio optima*. It may be that interns in seeking protection would expose themselves to a greater evil.

BOSTON HEALTH LEAGUE

ACTIVITIES OF THE PAST YEAR

The activities of the Boston Health League in promoting better health conditions in Boston during the past year were summarized by the reports of its various committees at the annual meeting of the Corporation late in May.

The health education committee has approved the formation of an Advisory Committee on Health Education for the City Health Department.

Mention has previously been made of the republishing and revising of the bulletin of the Summer Camp Committee. Over four hundred of these bulletins have been distributed. The Educational Committee on Cancer has as usual been very active, distributing much literature and arranging for educational talks on cancer. A social study of cases in each of the seven cancer clinics is now in progress.

The Committee on Social Hygiene has continued to sponsor the staff council on syphilis and gonorrhea and the consultation service of the Massachusetts Society for Social Hygiene. It is coöperating with the Massachusetts Society in the Boston aspects of a study of social hygiene instruction in the educational system.

Domiciliary medical care has been under considerable discussion during the past year, and the Committee on Techniques and Standards has recommended that a continuing committee on Domiciliary Medical Care for the Sick Poor of the City of Boston be organized as an integral part of the newly formed Hospital Council of Boston.

The Committee on the Needs of Ward Nine, where health conditions among the Negro population have been so unsatisfactory, sponsored an exhibit on nutrition in the fall. The Committee on Pneumonia has continued its efforts to reduce mortality from lobar pneumonia by urging prompt nursing care, and calling attention to the fact that the Community Health Association gives nursing service on a visit basis to persons not needing or unable to afford a full time nurse.

It is apparent that the Boston Health League is continuing to fulfill the important functions for which it was formed, to advise, to educate and to coördinate.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

CHAFFEE, E L S B, A M., Ph D Gordon McKay Professor of Physics and Communication Engineering, Harvard University His subject is "The Physics of High-Frequency Currents as Used in Medicine—Diathermy, Radiotherapy and the Electric Knife" Page 505 Address 130 Goden Street, Belmont, Mass

MISCELLANY

SCREW WORM LOSSES CHECKED IN THE
SOUTHEASTERN STATES

The screw worm made practically no gains in the Southeastern States during August. But the lull in its activity that occurs about the first of September if the weather is hot and dry does not mean the pest has quit for the season, says Dr F C Bishopp of the Bureau of Entomology and Plant Quarantine. When the weather is cooler and more rain falls, the screw worm flies will be back with renewed energy. They will remain aggressive until low temperatures of late fall or early winter drive them to hibernate.

Recent reports to Doctor Bishopp, who is in charge of the control campaign financed with a special appropriation of \$480,000, refer especially to infestation of animals.

Screw worm cases among human beings are not

uncommon in many parts of the South. Twenty-five such cases have been reported during the present season. People with exposed sores or wounds Doctor Bishopp says, take a long chance when they sleep out in the open with no protection against the screw worm fly. The screw-shaped worms that hatch from the eggs laid by the adult flies can soon turn a tiny scratch into a large deep wound. Sometimes the flies lay their eggs in the nasal pas-

sages of people suffering from catarrh or a nose injury. Swelling and soreness always accompany the activity of the worms that hatch from these eggs. The swelling or soreness of the nose of a person who has been exposed to fly attack is a signal to seek competent medical advice. These small hatching worms have been known to destroy the bridge of a person's nose—Excerpt from the *Bulletin of the Department of Agriculture*

ORGANIZED MEDICINE GOES ON THE AIR

A copy of an announcement which will appear in *Hygeia* for October 1935 is appended

This is evidence of the purpose of organized medicine to furnish practical instruction for use by the laity when confronted by emergencies of a medical nature. In order to promote the greatest possible interest in this movement physicians may have, displayed in their offices copies of this announcement. A few copies for distribution are in the office of the Boston Medical Library State Medical Societies may bring this information to the public through announcements in the daily newspapers

This plan is worthy of medical endorsement

DRAMATIZED RADIO PROGRAMS FOR MEDICINE AND HEALTH!

your health

ladies and gentlemen

This toast—through the music—each Tuesday at 5 00 P.M. Eastern Standard Time (4 00 P.M. Central Standard Time 3 00 P.M. Mountain Time) will introduce the new radio program of the American Medical Association. It will be offered over the Blue network of the National Broadcasting Company beginning October 1 1935. With the cooperation of the National Broadcasting Company a new type of program in vivid dramatic form with incidental music, is being developed, showing medical emergencies and how they are met!

The hero of the medical emergency the doctor who is available day and night for the protection and promotion of YOUR HEALTH is the real sponsor of this series of practical and entertaining health broadcasts

Each Tuesday—

“ ladies and gentlemen

CORRESPONDENCE

AN EXTRAORDINARY MEDICAL RECORD

Editor *New England Journal of Medicine*

The following quotation is from *The Countryman* a remarkable magazine published quarterly in London. It is full of the most unusual items among them many concerning medical history and I hope that physicians interested in unusual notes on the history of medicine and natural history may perhaps see it and derive as much pleasure from it as I have done. The quotation is from the current issue July September 1935

A REMARKABLE INSCRIPTION

I have presided in the chapel at Longhorough in the graveyard of which I copied the following inscription nearly forty years ago. I have also preached at the chapel at Wimeswold mentioned on the gravestone.

* In Memory of Sarah Johnson who died August 4th 1819 aged 28

S Johnson was tapped for Arcites 28 times 6 operations by Dr Vicars 12 by Mr Brown of Wimeswold

Here follow in ruled columns the quantities in gallons quarts and pints

Total in six years 310 gallons 1 quart 1 pint.

Kenneth Bond.

Surely this seems an all time record

Very truly yours

NUMBER 12

THE TREATMENT OF COMPOUND FRACTURE OF THE SKULL*

A Study of 185 Cases

BY DONALD MUNRO, M.D.†

INTRODUCTION Compound fracture of the skull occurs in roughly 105 per cent of all cases of skull and brain injury. In a group of approximately 900 head injuries, it is only one per cent less frequent than subdural hematomas and the two together comprise 22 of the 29 per cent of cranial injuries that require operative therapy. Such a large group of patients justifies more interest than has been accorded them in the past. It is the purpose of this paper to present figures which will demonstrate that such increased interest pays dividends in the form not only of lowered mortality but also of a great decrease in morbidity.

A review of the literature for the past ten years yields only one paper given over to an adequate exclusive consideration of the subject. This was written from Germany. The authors analyzed 169 cases treated over a period of twenty-three years. Their mortality (41 per cent) and morbidity (11 per cent) rates are high for this reason. The earlier poorly treated cases are not separated from the later ones which were operated upon under modern conditions and by modern methods except in a late result series of posttraumatic epileptics. Here the incidence was 6 per cent in the group treated by a modern closed débridement method as opposed to 12 per cent in a group of about the same size treated by the old open packed wound method. Operation in the first twelve hours with complete mechanical débridement and closure without drainage except where the frontal sinus is involved is urged. Grant¹ on the other hand advises only a modified débridement of the dura and brain only if cerebrospinal fluid is leaking. He drains all wounds. Nelson's Loose Leaf Surgery² does not list "compound fractures of the skull" in the index. What text there is on this subject is under "depressed fractures." Homans³ gives the subject a short paragraph advocating débridement in six hours with out drainage. If done later the cortex should be drained. In Lewis' Surgery⁴ prompt

débridement (within twelve hours) without drainage is advised. Large free fragments of bone are replaced if removed within this time after the accident. Other authors^{5, 6, 7, 8, 9} discuss the subject from the point of view of experience with a single case or as one that requires no explanation.

The Mortality Rate This paper is based on a series of 185 cases that have been collected from the records of the Boston City Hospital. Ninety-six of these were treated on the general surgical services in the thirteen years from July, 1922 to July, 1935. The remaining eighty-nine were treated on the neurosurgical service of the same institution during the five years from July, 1930 to July, 1935. The cases from the general surgical services were treated in a variety of ways. These included no operation, cleaning and sewing the scalp wound only, débridement of scalp wound only with drainage, and débridement of the scalp wound with varying degrees of débridement of the bone and rarely also of the dura but practically never of the brain. No cases were treated until they were out of surgical shock. The diagnosis was usually made by inspection with instrumental palpation through the wound. More recently though, palpation by the operator a gloved finger has replaced this method to a great extent. The operative technique varied greatly with the individual surgeon but it was only rarely that an adequate débridement was performed and even less rarely that a wound was closed without drainage. Where the scalp wound was treated at all on admission it was always shaved, scrubbed and mechanically cleansed at once. Such practices, however, may be fairly taken to represent an average cross section of the general surgical methods in use at the present time. By contrast, on the neurosurgical service all cases were theoretically diagnosed and treated by one standard method to be described in detail below. Any variation, when it occurred has been recorded against the outcome of the case as a technical error and has been duly considered in evaluating the results.

In the consideration of the comparative mortality of these two groups it became at once ap-

From the Neurosurgical Service of the Boston City Hospital.

†Munro, Donald—Surgeon in charge of the Neurosurgical Service, Boston City Hospital, Boston. For record and address of author see "This Week's Issue" page 546.

parent that true treatment mortality could only be ascertained after the elimination of those cases that were so severely injured on admission that all active treatment was out of the question. Therefore the admissions that died without treatment within twenty-four hours have been segregated from the rest of the group. This permits the compilation of mortality rates from two points of view for each series (Table 1).

resultant adherent scars between scalp and cortex, are considered inevitable consequences of this type of injury. These are all in fact the immediate end results of wound infection. The morbidity from sepsis in both series was therefore compared. The figures include only those patients that left the hospital alive as it was felt that these were the only cases in whom an accurate diagnosis of postinjury or postoper-

TABLE 1

Permissible Figures					25.0%	10.0%

*The number of untreated twenty-four hour deaths and the corresponding mortality percentages are only approximate in this group.

Based on the total number in each group the mortality rate in the general surgical series was 54 per cent as opposed to 31 per cent on the neurosurgical service, a difference of 23 per cent. With the cases which died in twenty-four hours eliminated, the difference is still 10.3 per cent lower in the neurosurgical group (17.5 per cent as compared with 27.8 per cent) though these totaled seventy-four cases as opposed to sixty-one and in spite of the fact that no case regardless of condition was refused treatment. It should be pointed out that all diagnoses in both groups that were unconfirmed either by operation or direct examination of the wound were verified in case of death through the courteous cooperation of Dr Timothy Leary, Medical Examiner of Suffolk County.

The Morbidity Rate The mortality rate in compound fractures of the skull is only half the story, however. Leaving out of consideration all problems of end-results beyond the actual period of hospitalization, the question of postoperative and postinjury sepsis must still be dealt with. It is well recognized that meningitis, encephalitis, intracranial abscess and healing of the scalp wound by granulation with

active sepsis could be made (Table 2). In both groups all wounds were considered septic that did not heal by first intention. In case drainage was inserted only the healing of the wound exclusive of the opening of the drainage tract was considered. The difference of approximately 52 per cent in the operated cases and 30 per cent in the non-operated cases speaks strongly in favor of the standardized method of treatment as a means of reducing the morbidity.

Operative Mortality and Morbidity Any consideration of a surgical procedure that involves operative interference must also include a study of the mortality and morbidity inherent in it. Again let me emphasize that the figures included herewith concern themselves only with mortality and morbidity during the patients' hospital stay. Table 3 summarizes these figures from both series and also includes the percentage of operated cases. In spite of the fact that more than 70 per cent of the neurosurgical patients were operated upon as opposed to less than one-half of those admitted on the surgical side, the operative mortality of the former is about 10 per cent below the latter, while the morbidity from sepsis has been reduced by more

TABLE 2
ANALYSIS OF MORBIDITY

	Total Treated	Operated				Not Operated			% Sepsis
		Total	Clean	Septic	% Sepsis	Total	Clean	Septic	
Total Series	104	85	58	27	31.7	19	10	9	48.2

than 50 per cent. It seems fair to conclude therefore that well-conceived operative therapy will not only of itself lower the death rates but will also, if properly carried out, reduce the occurrence of postoperative sepsis from three out

after their injury. The corollary to this is as pointed out below, that immediate emergency treatment of compound fracture of the skull is not only unnecessary but is actually dangerous. The one death from hemorrhage occurred on the

*The figures and percentages of operation and sepsis are only approximate in this group

of four cases to slightly more than one out of five cases

Analysis of Deaths A final test of the justification of a method of treatment and a corollary to the analysis in the preceding paragraph is found in a detailed study of the causes of death. Table 4 gives a tabular view of such figures in these two groups. It is in the main self-explanatory and needs emphasis only in one or two points chiefly because of their bearing on what

table and resulted from an inadequate appreciation of the dangers inherent in a fracture which crosses a cranial venous sinus. The deaths due to pneumonia and heart failure are self-explanatory.

Treatment In dealing with any method of treatment of compound fracture of the skull it is essential that certain fundamental principles be recognized and followed. These are both general and specific in nature. In general the oper-

TABLE 4
ANALYSIS OF DEATHS

	Total Treated	Operated		Not Operated		Sepsis			Causes of Death Operative			Miscellaneous			
		Clean	Septic	Clean	Septic	Meningitis	Brain Abscess	Sepsis	Medullary Edema	Surgical Shock	Hemorrhage	Diagnosis Missed	Extradural Clot	Pneumonia	Heart Failure
B C H Series	17	6	6	2	8	5	2	1		5		2	1		
N S Series	12	3	8	1		5	3		2					1	1

follows. The first and most important is the fact that in the general surgical services three cases died because the diagnosis was missed, two from the effects of the compound fracture and one from an extradural clot. The first two did not come to operation at all while the third was operated upon but so incompletely that the source of the clot was not recognized even then. The obvious implication is that the diagnostic methods as used on the general surgical services were inadequate. The second point has to do with immediate postoperative deaths. The majority of these were from surgical shock and occurred within twenty-four hours after the operation while medullary edema at a somewhat later time accounted for the others. The ratio of five to two emphasizes the fact that these patients were operated upon too soon

ator must always bear in mind that he is dealing not alone with a lesion of the bony covering but that the scalp, the meninges and the brain are all also always involved. If this conception is held firmly in mind the requirements of any method of treatment will be more apparent. Further more he must for his own protection locate the bony lesion in relation to the large cranial venous sinuses and also in relation to the frontal air sinuses. This knowledge will prevent him on the one hand from stumbling blindly into a fatal operative hemorrhage and on the other will permit him to place his incision in such a way as to provide for adequate drainage later. As far as specific procedures go the most important is to realize that if a debridement is attempted it should be 100 per cent in type and should not end in a drained wound. Any nec-

operative method as described is emphasized by the accompanying table 5. This lists the significant data in all the cases of death and sepsis in the neurosurgical group regardless of the method of treatment. Two deaths, one due to sepsis, occurred after operations that, as far as could be told, were technically perfect in both cases. The uncomplicated death was due to pneumonia in fifteen days after admission. That due to sepsis occurred in twenty-one days from a streptococcus hemolyticus meningitis in which the bacteria were demonstrated in the cerebrospinal fluid twelve hours after the operation. Other fatalities included two which were the result of an operation performed while the patient was possibly still in surgical shock. They were done twenty-eight and nineteen hours after injury respectively. All other deaths were secondary to infection except one in which an incidental heart failure was the cause.

The greatest single cause of postoperative sepsis was some type of major technical error in the performance of the operation. This occurred as the sole cause ten times, and was a factor in two other septic cases. This is 60 per cent of the entire group. The errors varied from parallel scalp incisions, and packing a wound to control bleeding, to failure to debride both bone and brain. Half of the twelve died and the other six had an average hospitalization of thirty-nine days, the maximum being seventy-eight and the minimum twenty-three. Improper handling of the wound on admission caused no deaths and no major sepsis but was associated with two infected scalp wounds in neither of which was any operative procedure carried out. Operations performed after the forty-eight hour period were the only cause of sepsis in four cases, three of whom died. The postponement was for nine days, four days, seventy-two hours and fifty-five hours after the injury respectively.

It is obvious that technical errors in operating are subject to correction and that operative interference at too late a time is inexcusable. It is theoretically possible therefore to calculate ideal mortality and morbidity rates for the method of treating compound fractures of the skull as described. For this purpose it is reasonable to consider eight deaths as preventable (all having been operated) and sixteen cases of sepsis as preventable, fourteen of them having been partially débrided. When revised in this manner, this neurosurgical series has a gross mortality of 23.5 per cent in a group of eighty-nine cases and including all cases dying untreated within twenty-four hours of admission. If these latter are excluded the theoretical mortality of treatable compound fractures of the skull in this series of seventy-two cases drops to 5.5 per cent. The operative mortality and morbidity in the sixty-four débrided compound fractures of the skull takes an equally striking drop. Here the mortality rate drops from 17.4

per cent to 4.6 per cent and the morbidity from sepsis from 23.4 per cent to 1.5 per cent.

CONCLUSIONS

1 From a series of ninety-six compound fractures of the skull admitted to the general surgical services of the Boston City Hospital during thirteen years, and lacking other confirmatory data it is suggested that the mortality of this injury as treated by the general surgeon has a gross figure of 54.1 per cent and a net figure of 27.8 per cent.

2 From a series of eighty-nine similar cases admitted to the neurosurgical service of the Boston City Hospital during five years and treated by a standardized method the actual gross mortality was 32.5 per cent and the net 16.6 per cent. It should be possible to reduce these figures further to the neighborhood of 23.5 per cent and 5.5 per cent.

3 The morbidity from sepsis in compound fractures of the skull when treated by general surgical methods ranges from a total of 75 per cent, through 65.6 per cent in the living operated cases to 58.3 per cent in the living unoperated ones.

4 The morbidity from sepsis in compound fractures of the skull when treated by the special method in use in the Boston City Hospital neurosurgical service ranges from a total of 23.4 per cent, through 13.2 per cent in the living operated cases to 28.5 per cent in the living non-operated ones. It should be possible to reduce these figures further to the neighborhood of a total of 1.5 per cent, through 0 per cent in the living operated cases but with the same 28.5 per cent in the living unoperated ones.

5 A method of treating compound fractures of the skull is described. Emphasis is placed on the care of the wound on admission, the length of the preoperative interval, the method and completeness of the débridement and the requirements of closure of the wound.

6 The cases that either died or developed sepsis in this neurosurgical service series are discussed in detail from the point of view of method and efficiency of treatment.

7 The maximum permissible mortality rate in compound fractures of the skull should be grossly not over 25 per cent. If the cases that died untreated within the first twenty-four hours of admission to the hospital are eliminated the mortality rate should not be over 10 per cent.

8 The maximum permissible operative mortality rate in treated compound fractures of the skull should not be over 10 per cent.

9 The maximum permissible morbidity rate from sepsis in treated compound fractures of the skull should be not over 5 per cent.

REPORT OF A CASE OF LEAD ENCEPHALITIS DUE TO TRIETHYL LEAD*

BY KARL M. BOWMAN, M.D.,† AND PAUL M. HOWARD, M.D.†

ENCEPHALITIS due to either tetraethyl or triethyl lead is quite rare and very few cases have been reported since the first group of about seventy cases in 1924 and 1925. It seems worth while, therefore, to present a case of triethyl lead poisoning.

The patient was a white married male of forty years. He was sent in to the Boston Psychopathic Hospital on September 12, 1934 by Dr. Joseph Anh who had made a tentative diagnosis of encephalitis from tetraethyl lead.

On admission the patient was disoriented, confused and had marked disturbance of memory for both recent and remote events with some tendency to confabulation. He could remember nothing that had happened during the past year, could not give a correct chronological history of his past life and could not recall an address or name after one minute. He gave his age as about thirty-seven. There was no disturbance of mood although he seemed somewhat restless, no special trends were elicited. There was no evidence of delusions or hallucinations but a few days later he apparently thought that he saw insects. There was no insight; the patient claiming that he was not ill and that his mental faculties were not impaired. The mental picture was that of an impersonal organic psychosis.

The physical examination showed a white male, five ft., tan in tall, weight 147 lbs., with evidence of recent loss. He appeared seriously ill. The heart, lungs, abdomen and extremities were normal. The throat was not injected although the patient complained of a sore throat and cough. There was no evidence of dehydration. Blood pressure was 110/80, the pulse rate was 80. The neurological examination showed a coarse tremor of the hands, arms and head and fine tremor about the mouth. The deep reflexes were equal and active. There were none of the classical signs of lead poisoning such as lead line, wrist drop or muscular weakness, colic, anemia or stippling of red blood cells.

The laboratory findings showed variable traces of sugar in the urine with some acetone and the slightest possible trace of albumen. Microscopic examination was negative. At the same time, the blood showed a nonprotein nitrogen of 48.4 mgm. per 100 cc. and a sugar of 141 mgm. per 100 cc. The spinal fluid sugar was 110 mgm. per 100 cc. These findings cleared up within a few days and there was no further evidence of faulty sugar metabolism. The other laboratory findings were negative at this

time. The spinal fluid findings including dynamics except for the increased sugar were normal.

Specimens were sent to Dr. Robert Kahoe of the University of Cincinnati Medical School and Dr. Lawrence T. Fairhall of the Harvard Medical School. Dr. Kahoe reported that on September 29 the blood showed 0.15 mgm. of lead per 100 Gm. of blood and that the urine showed 1.13 mgm. of lead per liter of urine by spectrographic method. On October 30 he reported that the blood showed 0.13 mgm. of lead per 100 Gm. of blood. However, this test tube had broken in transit so the results were not considered accurate. A urine specimen at the same date showed 0.10 mgm. of lead per liter of urine. A third specimen of blood collected November 16 showed 0.07 mgm. of lead per 100 Gm. of blood. A urine specimen collected at the same time showed 0.05 mgm. of lead per liter of urine.

Dr. Fairhall reported that two specimens of spinal fluid were questionable for lead; that a twenty-four hour specimen of feces on September 18 contained 0.3 mgm. of lead, a second twenty-four hour specimen on September 24 contained 0.77 mgm. of lead and a third twenty-four hour specimen of September 28 contained 0.77 mgm. of lead; that a urine specimen of 2200 cc. on September 25 contained 1.4 mgm. of lead and a second specimen of 4000 cc. of September 28 contained 0.19 mgm. of lead. In these specimens the lead was additionally separated as sulphate and identified positively as lead by microchemical analysis.

The history shows that the patient was of Scotch English descent, with no family history of mental or nervous diseases or alcoholism. Birth and early development were normal. He finished high school and took a night course to accounting. He held various jobs and was considered a conscientious and efficient worker. For the past year he had worked for an oil company and recently had worked at cleaning gasoline tanks. In 1923 he had an appendectomy and in 1925 a light attack of pneumonia. Otherwise there was nothing of significance in the medical history. He was married in 1921. In personality the patient was described as cheerful, energetic, industrious, popular and even-tempered. The exact details leading up to his illness were not entirely clear. The patient was employed cleaning out gasoline storage tanks. He wore an asbestos suit and a gas mask connected with a pipe from an oxygen supply. His duty was to remove the crust or scale from the sides of the tank after they had been emptied. Between August 20 and September 4 he entered nine gasoline tanks. About August 21 to 23 he complained that he could not smoke on account of burning in the area nose and throat. He also said that there was something wrong with the air supply in his gas mask. On August 30 head ache and insomnia developed. He began to lose weight rapidly and complained of great body fatigue. On September 5 he collapsed while at work was quite pale but managed to stagger about. He was

*Read before the Boston Society of Psychiatry and Neurology, November 15, 1934.

†Howard, Karl M.—Assistant Professor of Clinical Psychiatry, Dept. of University School of Medicine, Howard Paul M.—Intern Neurological Service, Boston City Hospital, 1935. For records and addresses of authors see "This Week's Issue" page 556.

taken to a general hospital, where he was kept until the next day and then sent home. On September 6 he was perspiring profusely, had headache, and again collapsed. On September 7 he was weak and confused, and showed mental symptoms. His insomnia had continued throughout this period. On September 8 he was very restless. On September 9 his restlessness continued and he showed marked memory impairment. This picture continued until the time of his admission to the Boston Psychopathic Hospital on September 12.

After admission to this hospital the patient grew worse rapidly. He began sweating frequently and profusely. He would lie on his bed, rolling his head back and forth in a fashion sometimes seen in rickets. The temperature which was normal on admission rose to 102° and the white blood count which was 6,400 on admission rose to 18,000. He became practically comatose with absent reflexes. There was an area of hyperesthesia to light touch over the lumbar region. Deep pressure, however, seemed to cause no pain. There was vague generalized abdominal tenderness. The only signs elicited in the chest were that the breath sounds were heard better on the left side than the right. This condition soon cleared up, the fever fell by lysis, the confusion disappeared and memory improved.

On October 5 he was transferred to a convalescent ward. It was noted at this time that the temperature had been normal for a week and that the white blood count was normal. On October 15 it was noted that he was improving steadily. His memory appeared fairly good for past events, but quite poor for recent events. He could not remember having worked at any time cleaning gasoline tanks. A special memory test was done on this date using the Wells memory examination. It was noted that the patient was very cooperative, that he worked with excellent effort and with considerable interest. Memory for recent events was especially poor, scoring below average and, in two items, below the normal limits. Memory for old material was good. These findings were considered consistent with the clinical history of the case and were felt to represent the type of memory defect one would expect in a case of this type.

About October 20 the patient developed a cough and was put to bed. It was noted at this time that he had been quiet and cooperative, that he seemed alert and cheerful, talking freely with others and being quite sociable. No delusions or hallucinations were present. He seemed definitely confused about events in his past life and could not get the order of his occupations correctly. He developed many more physical symptoms from this time on. By October 26 it was noted that he had a temperature of 101.8°, skin was moist, there was considerable cough, inguinal and epitrochlear adenopathy was noted. There was slight tenderness over the epigastrium.

On October 29 a blood examination showed a hemoglobin of 76 per cent, Sahli. The red blood cells were 3,580,000, the white blood cells 19,000, 70 per cent being polymorphonuclears, the smear was normal. On October 30 an x-ray of the chest was reported by Dr W K Coffin to indicate marked pathology in the chest, suggesting bronchopneumonia, pneumonitis, abscess without cavity, or even neoplasm.

He was seen on November 3 by Dr S William Marlowe who noted that there was marked inequality of chest expansion, the right side lagging and not expanding so much as the left, the right supraclavicular fossa was deeper than the left. The heart was not enlarged nor displaced. Posteriorly there was dullness at the right apex with no alterations in breath sounds or vocal fremitus. After coughing,

a few râles were heard at the right apex. No other findings were made out. Tuberculosis was considered the most likely explanation and repeated sputum examinations were done which were negative.

By November 8 the temperature had dropped to 99° and remained normal after that time. The blood examination on that date showed a hemoglobin of 65 per cent, Sahli. The red blood cells were 3,800,000, the white blood cells 22,800, 78 per cent being polymorphonuclears, the smear was normal. The

FIGURE 1 'Film No 1 X-Ray Report. There is an extremely dense extensive and mottled, and indefinitely bounded shadow surrounding and radiating from the right hilum and occupying an area the size of a large flattened orange with bands and striae prolonged raggedly outward and upward to the axilla. In the left side though a somewhat similar but far less dense shadow is seen. Heart negative. Findings suggest a distribution, largely peribronchial though there is some parenchymal involvement. Probably not Tbc but it cannot be altogether excluded. bronchopneumonia, pneumonitis, abscess without cavity, possibly even neoplasm and syphilis are to be considered. W K Coffin 10/31/34

patient's physical condition improved steadily from this time on. He was given iron and ammonium citrate for the anemia and by November 24 the hemoglobin was 80 per cent, Sahli. The red blood cells were 5,010,000, the white blood cells, however, were 20,500, 72 per cent being polymorphonuclears and the smear normal. The urine had been essentially negative during this period.

Two further x-rays of the chest, an oblique chest made on November 13, and a six foot chest plate made on November 22 showed a less intense shadow in the right lung near the hilum, with slight lessening of density in some areas in the right lung. No decided clearing up was noted. These three x-ray plates were examined by Dr M C Sosman of the Peter Bent Brigham Hospital who reported as follows:

"I think it is a very difficult series of plates to read, and in fact cannot tell exactly what this process is.

"It is probably an inflammatory process. I do not think it is tuberculosis or malignancy. The regression shown between the two series of plates is against malignancy. It is possibly a fungus infection and I suggest culture for this. There is something of the appearance of a pneumoconiosis. Was he in a dusty trade? Very possibly it is a bronchopneumonic type of pathology. There is a possible connection between this and his recent exposure to tetraethyl lead."

On November 9 a second memory test showed definite improvement, the memory quotient having risen from ninety-two per cent on the first test to 107 per cent. From this time on convalescence has been gradual with no remissions.

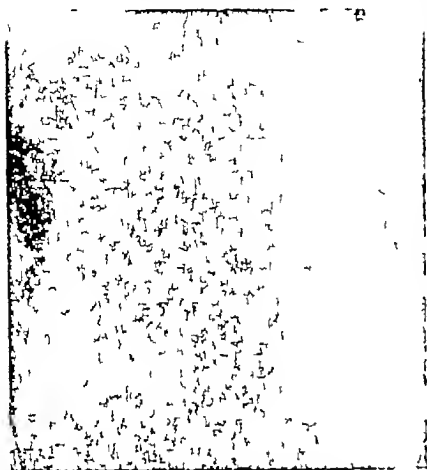

FIGURE 2. Film No. II. X-ray Report. There is the general appearance as before but the intensity of the right lung near the hilum is somewhat less dense than and apparently there is a somewhat wider diffusion of the clouding both right and left. W. K. Conn. 11/15/21

On November 27 it was noted that the patient continued afebrile that there were no night sweats but that there was considerable cough and sputum. The right chest showed dullness posteriorly breath sounds were heard better on the left side.

FIGURE 3. Film No. VI. X-ray Report. Marked improvement since last time. The individual bronchial markings are now quite easily traceable and much of the parenchymal infiltration has cleared. W. K. Conn. 1/19/22

than the right anteriorly. There seemed general improvement both physically and mentally.

The patient's weight curve is of some interest. On admission September 12 he weighed 142 pounds.

There was a drop to 132½ pounds by October 5 following this there was a slight gain in weight so that on October 19 it was 135 pounds. With the acute illness at this time the weight dropped to 125 pounds on November 23. Following this there was a steady rise so that on December 7 it was 130½ pounds, December 23 141 pounds, January 4 148½ pounds, January 31 157½ pounds.

There has been steady mental and physical improvement. A third memory test on January 26 showed a memory quotient of 118 per cent. The general physical and laboratory examination from examinations made during the last week in January were essentially negative. The urine showed a one plus sugar but the blood sugar was 87 milligrams per 100 cc of blood. It was also noted that there were ten white blood cells per high power field in the urine with some clumps which suggested that there might be some pyelitis. Temperature however was quite normal and there was no localized tenderness.

An x-ray of the chest on December 8 showed definite improvement of both lungs although there was still a great deal of infiltration particularly on the right. Three more x-rays taken on January 7, 16 and February 9 show further improvement.

The treatment in this case consisted of forcing fluids and the use of light metals such as calcium and magnesium. It would seem that this patient entered the hospital with a lead encephalitis due to the inhalation of tri-ethyl lead. The reason for assuming that it was due to tri-ethyl rather than tetraethyl is a personal communication from Dr. Robert A. Kehoe, which is as follows:

"I am taking the liberty of discussing briefly one point in the case upon which there seems to be some doubt, or perhaps misunderstanding. It seems to be your idea that appreciable quantities of tetraethyl lead may remain on the sides of gasoline storage tanks, and that workmen may be exposed both to this tetraethyl lead and to its decomposition products. This is not quite the situation and I should like to describe, therefore what happens inside these storage tanks.

"First let me point out to you that the evidence adequately demonstrates measurable amounts of tetraethyl lead (in the employed concentrations) are not absorbed out of gasoline by human beings within tanks or outside of them, either through skin contact or inhalation. Thus the question of tetraethyl lead does not enter into the problem as such under conditions in which gasoline containing tetraethyl lead in the commercial concentrations is involved. The following conditions must be pictured. Gasoline containing tetraethyl lead is allowed to stand for comparatively long periods of time (years) in storage tanks which have a layer of water at the bottom. The decomposition of the tetraethyl lead, which takes place mainly at the surface in the absence of light, results in the formation of finely divided tri-ethyl lead compounds which are only slightly soluble in gasoline, and in water. Thus finely divided material slowly separates out and small quantities of it are deposited in the scale on the sides of the tank.

Most of it, however, settles to the bottom of the tank, passing through both the gasoline and water layer, and is deposited along with debris from the sides of the tank in the form of a sludge. This entire process is so slow as to be insignificant over short periods of time but the tanks often go uncleaned for years, during which time they are used for the storage of one batch after another of gasoline. Thus after one or more years, there may be a significant amount of material on the bottom of the tank, which is finely divided, and which is relatively high in its lead content, such lead being in part (apparently up to as much as two per cent in our observations) composed of tri-ethyl lead compounds. There is also a measurable quantity of tri-ethyl lead compounds in the rust and scale on the tank. There are only traces of tetra-ethyl lead since tetraethyl lead does not separate out of its true solution in the gasoline.

"When such a tank is cleaned, if it is emptied out or steamed out and then allowed to air until the sides are dry, and the sludge has been partially dried, any attempts to remove either the scale or the sludge in this dry state result in the dispersion into the atmosphere of finely divided material including tri-ethyl lead salts. These salts make themselves known by their irritating effect upon the eyes and mucous membranes of the nose and throat. They even produce some burning and stinging of the skin. They are absorbed from the pulmonary surfaces with much greater rapidity than most inorganic lead compounds, and due to their chemical properties they are deposited in the tissues of the body in much the same fashion as tetraethyl lead. Their physiological effect is like that of tetraethyl lead. They produce, therefore, a fulminating type of lead intoxication with predominant central nervous system symptoms. Coincident with the rapidity of their absorption, they are apparently excreted somewhat more rapidly than most lead compounds. As a consequence, in both animals and men, lead excretion reaches a very high level shortly after exposure, and falls off much more rapidly than is the case with the more usual lead compounds.

"I have gone to some length to explain this matter because it seems quite clear to me that unless some unusual circumstance occurred, the explanation of the illness of Mr W is that he was exposed to such materials in a partially dry state, and either had an unsatisfactory mask or did not make use of it continuously during the period in which he worked.

"This is the only situation I know in which significant amounts of any lead compound separate out of gasoline containing tetraethyl lead, and it is of importance because it provides an occupational hazard at this one specific point. We have investigated the extent of the deposition which occurs in tank cars used for the trans-

portation of leaded gasoline. Here the situation is different not only because of the rapidity of turn-over of the contents, but also because there is no water layer in tank cars to act as a continuous means of separating out the tri-ethyl lead compounds. The tank cars, therefore, are found to contain only insignificant traces of these compounds."

SUMMARY

It is well recognized that tetraethyl lead may produce encephalitis and that mental symptoms form a prominent part of the picture. In fact, when the first series of cases were reported in New Jersey in 1924, ethyl gasoline was called "looney" gas. The symptoms in order of frequency are as follows: Insomnia, lowered blood pressure, subnormal temperature, anorexia, nausea, bodily weakness, abdominal cramps, unaccustomed or annoying dreams, decided loss of weight, slow pulse, headache and tremors. Kehoe² reported a series of cases in 1925 in which he emphasized that the clinical picture is different from that usually seen in lead poisoning. He stated that stupor and lead line occur only infrequently and not early in the disease, that the mode of entrance was by inhalation or directly through the skin. He stated that in some cases the mental picture resembled delirium tremens with the patient being overactive, over talkative and suffering from hallucinations. It is generally agreed that tetraethyl lead combines more readily with nervous tissue than do other forms of lead, hence one is likely to get a sudden attack of lead encephalitis without the ordinary signs of chronic lead poisoning. Kehoe² reported in 1934 that tri-ethyl lead may be inhaled in the form of finely divided dust by workmen cleaning the interiors of gasoline tanks with lead absorption and acute intoxication following. He states that the tetraethyl lead which is left on the sides of the tank decomposes after long standing to form crystalline tri-ethyl compounds. Apparently the clinical picture from tri-ethyl lead is similar to that from tetraethyl lead, and on the basis of Kehoe's report and personal communication it would seem that our patient had developed a lead encephalitis due to inhalation of tri-ethyl lead.

The interpretation of the pulmonary condition does not seem easy. Since tri-ethyl lead is intensely irritating and the patient presumably inhaled sufficient to produce a lead encephalitis, it is possible that the lung condition was produced by tri-ethyl lead. Dr Sosman suggests this from his interpretation of the x-ray plates. Dr Kehoe in a personal communication doubts the likelihood of this occurring. The length of time that ensued between the inhalation of the tri-ethyl lead and the development of the acute pulmonary signs, namely about six weeks, would also seem to argue against it. On the other

hand, it has been agreed by everyone who has examined the patient and the x ray films of the chest, that the picture is atypical and does not conform to the usual picture of any of the well recognized lung conditions. Without attempting to argue the matter further we merely raise this question.

The patient was also seen by Dr Joseph Aub and Dr Alice Hamilton.

DISCUSSION

DR. JOSEPH AUB. It is important to remember that the whole picture of lead poisoning from organic lead compounds is entirely different from poisonings by inorganic compounds. The peripheral manifestations seem to be largely lacking and lead colic and wrist drop do not seem to occur while stippling in the blood only appears long after the acute cerebral abnormalities produced by these organic compounds. Kehoe has shown that often to fourteen days the distribution of the lead from lead tetraethyl differs little from that of inorganic compounds but Gettler was able to find lead tetraethyl in the brain in a patient who died of poisoning from it. In the patient under discussion tonight, considerable quantities of lead could be isolated from the urine thereby showing that he had absorbed toxic amounts of some lead compound. While I have heard of other cases with severe mental disturbance such as this patient showed, most of the patients I have seen before have had only mild delusions and this patient stands out as unique in my experience in the severity of his symptoms with recovery.

DR. ALICE HAMILTON. I do not think I can add anything to this case except to review the history of tetraethyl lead. I heard of it first in 1922 when an expert from the du Pont Company asked me what I knew about it. I said I knew nothing and asked him what the symptoms were as he had seen them. He described an acute cerebral form of plumbism which was not encephalopathy as we know it but resembled delirium tremens and he said that they held the ethyl radicle responsible not the lead. A little over a year later the situation be-

came a matter of sensational publicity when some twenty eight severe cases occurred in New Jersey in the du Pont Works and in the Standard Oil Works where the compound was produced. The newspapers took it up the health services of several states threatened to forbid the use of ethyl gasoline the story crossed the ocean, questions were asked in the British Parliament, and Switzerland forbade the importation of ethyl gasoline. It was not so much the danger to the makers and blenders that aroused this excitement, but the fear that the lead discharged from motor engines might be a danger not only in garage work but in the streets for in the course of combustion tetraethyl lead is changed to the chloride or bromide (according to the carrier used) both of which are unusually toxic compounds and are discharged in the exhaust gas. These public protests moved the purveyors of ethyl gasoline to ask the Public Health Service for a scientific study of the possible danger to the public, and this was done. The Service attacked the problem in a very practical way. They examined four groups of men.

First, taxi drivers who had never used lead gasoline, secondly, taxi drivers who had used it for two years, thirdly, mechanics in garages where it had never been used, fourthly, mechanics in garages where it had been used for two years, and fifthly, a control group of storage battery workers who were exposed to a known lead hazard of unusual severity. The investigators found what they considered evidence of lead poisoning only in the control group and evidence of lead absorption in the fourth group but not in any of the other three. Kehoe of Cincinnati and his colleagues had previously made a similar study of filling station attendants and garage mechanics and had come to the same conclusion. The Public Health Service then announced that there was no reason why ethyl gasoline should not be put on the market. Some time later a British Royal Commission examined these findings and confirmed them. The Public Health Service has ordered the labeling of all pumps delivering ethyl gasoline and has arranged with the purveyors for an investigation of every case of supposed plumbism resulting from contact with it. Leake of the Service, and Kehoe of Cincinnati have followed up all these cases and in 1932 I was told by the former that ninety four illnesses in seventy two individuals had been investigated but in none was lead found to have played a part. The present case belongs in the category of the early cases and is for that reason an interesting rarity for under present conditions one would look for such an acute poisoning only as the result of an unusual combination of circumstances.

That there is danger in the use of this compound is recognized and vigilance must not be relaxed.

ADJUSTMENTS DURING FOUR YEARS OF PATIENTS HANDICAPPED BY POLIOMYELITIS

BY ELLEN H. BARBOUR*

THIS follow up study was made with the purpose of determining the physical improvement and the emotional adjustment during a period of four years, of sixty children who were victims of infantile paralysis. In 1930 in an article published in this *Journal* (207: 1195 [Dec. 29] 1932) the degree of paralysis of these

children was described in social terminology. Briefly they were classified under the following headings: educationally paralyzed implying that the individual was paralyzed to such a degree as definitely to impede his educational progress, occupationally crippled meaning that although the child could lead a quite normal childhood there would be a great possibility of his paralysis prohibiting him from certain occupations in later life and socially handicapped a disfiguring paralysis which although it

* Ellen H. Barbour—Social Worker at Clinic for Study of Growth Development of Normal Child, Harvard School of Public Health. For record and address of author see "This Week's Issue," page 515.

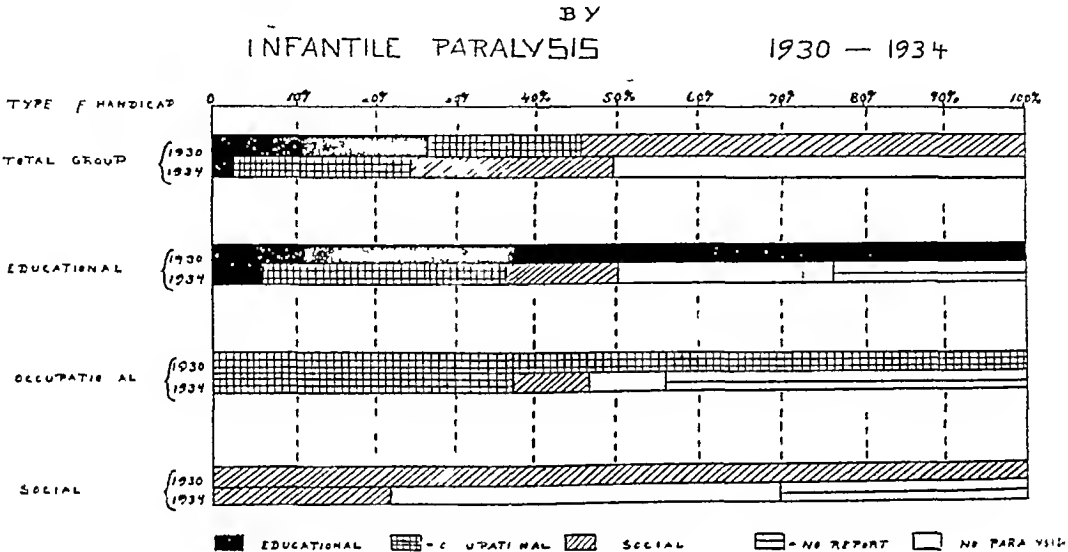

did not interfere with his physical life, might be a source of social embarrassment to him

All the children, with but two exceptions, received approximately the same treatment respective to their individual needs, either in their homes or at hospital clinics. The accompanying chart shows the relative proportions of the three groups of handicaps in 1930 and their redistribution in 1934. In 1930 over one-half of all the children were in the social paralysis group, approximately one-fourth fell in the most severely crippled, educational group and a little less than one-fifth were described as occu-

dicate that the socially paralyzed child has an excellent chance of being completely normal at the end of four years of treatment

The scholastic retardation was an interesting social factor of this study. Twenty-five out of forty children, at the end of four years, were not educationally retarded, nine were one year behind, four were two years and two were three years behind their classes. One of the two last mentioned attends the school for crippled children in Canton where she is rapidly making up her educational deficiency, and the other has undergone so many operations that,

REDISTRIBUTION OF TOTAL GROUP OF PATIENTS HANDICAPPED

REDISTRIBUTION OF TOTAL GROUP OF PATIENTS HANDICAPPED

BY

INFANTILE PARALYSIS 1930 — 1934

TYPE OF HANDICAP	POLIOMYELITIS PATIENTS			
	CONDITION IN 1930		CONDITION IN 1934	
	NUMBER	PERCENT	NUMBER	PERCENT
TOTAL	60	100%	41	100%
EDUCATIONAL	16	26.7	1	2.4
OCCUPATIONAL	11	18.3	9	22.0
SOCIAL	33	55.0	10	24.4
NO PARALYSIS	0	0	21	51.2

pationally handicapped. In the 1934 redistribution the paralysis of one-half of the total group had disappeared and one-half of those still crippled had only the mildest degree of paralysis. Slightly more than one in five were occupationally crippled and only one in fifty was severely limited in motion.

The charts also indicate the changes that have occurred during these four years in the groups. The educationally paralyzed seem to redistribute themselves either in the occupational or no-paralysis groups, with relatively few in the social class. The occupationally handicapped show the least change and the marked decrease of the social group would seem to in-

although between operations he is quite able to attend school, he has not yet succeeded in finishing one scholastic year since 1930. The twenty-one children who have completely recovered from the disease seem to have no darker memories of it than an attack of measles. They are a normally happy group, one of whom is described by his school-teacher as "the happiest boy in the class". Six out of the twenty children who are still paralyzed are emotionally maladjusted to their handicaps. The factors causing individual unhappiness may be more clearly discerned by the following brief case histories.

CASE 1 B P., a fourteen year old girl of good home environment, was left four years ago with a complete paralysis involving the facial nerves as well as those of her body. Today the only traces left of the paralysis are a slight limp when fatigued and a twitching of the right side of the face when she becomes nervous or embarrassed. Nevertheless she is extremely sensitive and bitterly resents any inference that she is not so strong as her sisters. As a result of this attitude she often overdoes to prove that she is normal. Whereas formerly she had a sunny disposition she is now touchy and irritable due to a constant condition of fatigue. Her age coupled with her particular type of paralysis are probably the two most important factors in her emotional maladjustment.

CASE 2 M P. now thirteen years old was left with a paralysis of the right forearm and wrist. Her condition has not greatly changed during the last four years. Her arm is still useless and is noticeably smaller than the left. Any occasion, such as meeting people, which calls for shaking hands discloses her infirmity and causes her great embarrassment. She retreats rather than face that painful ordeal. As in case 1 probably the two paramount causes of her unhappiness are her age and her particular type of paralysis.

CASE 3 Both legs of R S., an eight year old boy were completely paralyzed by the disease. His parents displayed such ignorance and stubbornness in refusing to permit the operation advised by the hospital and in ignoring the offer of suitable braces by the social service department that action was threatened by the Society for the Prevention of Cruelty to Children. As a result of these controversies the boy is completely unadjusted emotionally and physically to his handicap. He is very sensitive cries easily and refuses to play with other children. The smallness of his brace undoubtedly causes him

some physical discomfort. The parents attitude of ignorance and stubbornness is surely the most important reason for his unhappiness.

CASE 4 M. K., a married man and the father of two small children suffered from a weakness of the right shoulder and leg. During the past four years there has been but little improvement. Because of his physical disability he has been unable to retain such employment as he could find during this period. At the time of the 1934 visit, this family was receiving welfare aid and the patient's state of mind could only be described as desolate. Economic insecurity as a result of infantile paralysis is the direct cause for this individual's unhappiness.

CASE 5 P B was badly crippled when only two and one-half years old. Both legs were left quite useless. Now he walks with great difficulty in braces. His mother never permits him out alone since his balance is so precarious. She hesitates to take him among people because he is very sensitive and shrinks from even the stranger's casual glance. This little boy's hypersensitiveness would seem to be the main cause of his unhappiness.

CASE 6 Five year old E. J. an only child of adoring parents suffered a paralysis of the right shoulder and arm. His condition has improved but little during the last four years. His parents took it so tragically and treated him as such an object for pity that some of their attitude was transmitted to the child until he now feels himself to be an irrevocably damaged person. His physical disability has grown to such proportions in his parents' minds and hence in his own that he can think of little else. His fear of this "terrible thing" which has happened to him is pathetic. Obviously an only child devoted parents and poor psychology are the determining factors in this child's emotional maladjustment.

A METHOD OF REPAIR OF FEMORAL HERNIAE BY A FASCIAL STRIP FROM THE APONEUROSIS OF THE EXTERNAL OBLIQUE MUSCLE

BY GEORGE A. MARKS, M.D.*

It has been said that at least one hundred methods of repair of femoral herniae are recorded in medical literature. One hesitates to add another method to the list. The procedure to be described below is offered, therefore, as a slight modification on a method already existing in many variations.

It is true that many femoral herniae are repaired successfully by simple ligation of the sac without attempt to obliterate the femoral opening. Recurrences are reported, however, in series by Watson, Coley and Erdman to vary from 4.85 per cent to 17 per cent.

Strangulation is dangerous in this type of hernia because of the small diameter of the ring. The Richter's type of strangulation in which only a portion of the wall of the intestine is involved seems especially apt to occur in femoral herniae.

The femoral opening by virtue of its anatomical construction lends itself with difficulty to obliteration. It is bounded anteriorly by the melastolic ligament of Poupart, medially by the fixed knife-like edge of Gimbernat's ligament and posteriorly by the pectineus fascia and muscle. On its lateral aspect lies only the femoral vein. None of these structures may be displaced, in the average case, with the necessary ease to insure permanent approximation, nor are they capable of exerting the sphincteric action found in the structures surrounding the inguinal rings.

Prior to 1890 ligation of the hernial sac alone was done. In 1892 Berger and in 1894 Bassini, added the important feature of closure of the femoral canal and ring. They sought to accomplish this by suture of Poupart's ligament to the pectineal fascia (Cooper's ligament) and suture of the falciform process to the pubic portion of the fascia lata. Later, Coley em-

George A. Marks, M.D., Assistant in Surgery, Massachusetts General Hospital. For record and address of author see "This Week's Issue" page 555.

ployed the purse-string suture of kangaroo tendon or chromic catgut to approximate these structures. Blake modified this by using a mattress suture for the same purpose, while Cushing placed two purse-string sutures in the same location.

Annandale, in 1876, had described the approach which splits the aponeurosis of the external oblique muscle, but this was not used extensively until Ruggi (1892), Lotheissen (1898), Gordon (1900) and Moschcowitz (1905) brought about various modifications.

Nelson's System of Surgery lists a number of curious procedures for the repair of this hernia, among them, the tacking of Poupart's ligament to the pubic bone by a metal staple and the use of heteroplastic flaps of fascia, periosteum, bone or muscle.

Two requirements must be satisfied to prevent the recurrence of a hernia repaired surgically, the defect must be obliterated by firm, relatively inelastic structures displaced from their original anatomical alignment as little as possible, these structures must be held in position by methods which interrupt as slightly as possible their viability and function. The principles of asepsis and hemostasis, of course, must be obeyed. In the methods described before, those which entail the approximation of Poupart's or Gimbernat's ligament to the pectineus muscle and fascia, attempt to displace an inelastic, firmly fixed ligament and anchor it to a structure which has very little strength. The resulting tension should defeat the purpose. If laxness in Poupart's ligament allows easy approximation to the pectineal fascia, this usually means a ligament of little durability.

Gall's technique of repair of herniae by the use of autogenous fascia removed from the thigh is widely recognized. McArthur's modification for inguinal herniae employs a strip of fascia from the aponeurosis of the external oblique muscle, left attached at its insertion in the rectus sheath.

Modification of this latter technique suggested itself as suitable for use in the repair of femoral herniae. By the modification described below, a sufficiently long fascial suture is available for obliteration of the femoral space without extending the operation to include removal of fascia from the thigh. While the latter maneuver is not a risk in younger patients, its avoidance is desirable in the older patients among whom the incidence of femoral herniae is high.

Technique An oblique incision through the skin is made parallel to Poupart's ligament and carried down to the fascia of the external oblique muscle. The position of this incision allows inspection of both sides of Poupart's ligament and exposure of the femoral opening

from below if it is found necessary. Small hernial sacs may be pulled up from inside if not incarcerated.

The fascia of the external oblique is then split in the direction of its fibres. The contents of the inguinal canal are gently separated from the medial aspect of the ligament of Poupart until the femoral ring and the hernial sac are exposed. Further gentle blunt dissection around the ring is usually enough to allow the sac and its contents to be drawn in. If this is difficult or entails unwarranted manipulation, pressure on the sac from outside may be applied. In the event that this does not reduce the hernia, a small incision through the medial aspect of the ring in the direction of Gimbernat's ligament may be made.

After reduction, the sac is opened, the excess excised and the peritoneum closed by a purse string, or running suture, reinforced by one or two mattress sutures.

A ribbon, five mm in width, is then split from the upper leaf of the divided external oblique fascia, leaving it attached at its insertion in the rectus sheath above the spine of the pubis. Its outer end is cut across and fixed to a fascial suture needle with silk.

The fascial suture thus constructed is then threaded along the inner aspect of Poupart's ligament until the medial side of the femoral ring is reached. From this point of departure, the suture is passed across the opening two or three times, depending on its diameter, anchored below each time by a bite which includes pectineus fascia, muscle and the underlying investment of the ramus of the pubis. At each crossing of the opening, the needle should transfix the strand just laid, approximating the strands and tending to obliterate small clefts. The terminal portion of the strip is usually long enough to allow a final interweaving in a horizontal or oblique direction. The end of the strip is anchored firmly at any point of the ring formed by Poupart's ligament by silk sutures. Any of the interstices left in the weave at this time should be closed by interrupted silk sutures.

The split in the external oblique fascia is closed by interrupted imbricating stitches, the superficial fascia and subcutaneous layer approximated by a fine running stitch of plain No. 00 catgut and the skin edges plicated with silk.

Three cases, one bilateral, have been repaired by the writer and two others by another at his suggestion, using the technique described above. The small number of cases, and the brevity of the postoperative interval, prevent conclusions being drawn.

Summary A technique for repair of femoral herniae by the use of a strip of autogenous fascia from the external oblique aponeurosis, left anchored at its inner aspect, is described.

NEW HAMPSHIRE MEDICAL SOCIETY

CONGENITAL PYLORIC OBSTRUCTION*

BY CHESTER F. MCGILL, M.D.†

THE earliest reference to congenital pyloric obstruction was by George Armstrong in England in 1777. The case reported was the third similar one in the same family. All three died.

Again, Ezekiah Beardsley of Connecticut, in 1787, described in most interesting detail the clinical symptoms and postmortem findings in a five year old with symptoms dating from infancy. According to Garrison's History of Medicine, Beardsley's account appeared in the earliest volume of medical transactions issued in this country entitled "Cases and Observations by the Medical Society of New Haven County in the State of Connecticut." Dr Beardsley writes, "A child of Mr Joel Grannis a respectable farmer in the town of Southington, in the first week of its infancy was attacked with a puking, or ejection of the milk and of every other substance it received into its stomach, almost instantaneously and very little changed. The faeces were in small quantity and of an ash color which continued with little variation until its death. For these complaints a physician was consulted who treated it as a common case arising from acidity in the prima via, the testaceous powder and other absorbents and correctors of acid acrimony were used for a long time without any apparent benefit. The child, notwithstanding it continued to eject whatever was received into the stomach, yet seemed otherwise pretty well and increased in stature nearly in the same proportion as is common to that state of infancy but more lean with a pale countenance and a loose and wrinkled skin like that of old people. Thus as nearly as I can recollect at this distance of time, was his appearance and situation when I was first called to attend him, he was now about two years old. I was at first inclined to attribute the disorder to a deficiency of the bile and gastric juices, so necessary to digestion and chvification, joined with a morbid relaxation of the stomach, the action of which seemed wholly owing to the weight and pressure of its contents, as aliment taken in small quantities would often remain in it, till by the addition of fresh quantities, the whole or nearly all, was ejected, but his thirst or some other cause most commonly occasioned by swallowing such large draughts as to cause an immediate ejection, and oftentimes before the cup was taken from the mouth. It did not appear

that he was attended with nausea or sickness at his stomach, but he often complained that he was choked and of his own accord would introduce his finger or the Probang so as to excite the heaving of the stomach and an ejection of its contents, the use of this instrument was generally necessary if the stomach did not of itself, in a few moments, discharge its contents. The choking would in that space of time become almost intolerable which by this discharge was almost entirely removed. In this situation, with very little variation of symptoms he continued until death closed the painful and melancholy scene when he was about five years of age. He was uncommonly cheerful and active considering his situation. A number of the most respectable medical characters were consulted, and a variety of medicines were used to little or no effect. His death, though long expected, was sudden which I didn't know until the second day after it took place. This late period, the almost intolerable stench, and the impatience of the people who had collected for the funeral, prevented so thorough an examination of the body as might otherwise have been made.

On opening the thorax the esophagus was found greatly distended beyond its usual dimensions in such young subjects, from one end to the other of this tube between the circular fibers which compose the middle coat, were small vesicles some of which contained a tablespoonful of a thin fluid like water, and seemed capable of holding much more. I next examined the stomach which was unusually large the coats were about the thickness of a hog's bladder when fresh and distended with air. It contained about a wine pint of fluid exactly resembling that found in the vesicles before mentioned and which I supposed to have been received just before his death. The pylorus was invested with a hard compact substance or scirrhus which so completely obstructed the passage into the duodenum as to admit with the greatest difficulty the finest fluid whether this was the original disorder, or only a consequence, may perhaps be a question. In justice to myself, I ought to mention that I had pronounced a scirrhus in that part for months before the child's death.

"On removing the integuments of the abdomen, I was struck with the appearance of the vesica fellea, which was nearly five inches in length and more than one in diameter, it lay transversely across the abdomen, and was bedded into the small intestines, which were sphacelated wherever they came in contact with it. Its con-

Read at the Annual Meeting of the New Hampshire Medical Society at Manchester, May 7, 1915.

†McGill, Chester F.—For record and address of this see "This Week's Issue," page 545.

tents were rather solid than fluid and resembled flesh in a highly putrid state, its color was that of a very dark green, like the juice of a night-shade berry, and a fluid of the same color exuded through its sphacelated coats. The necessity there was of entering the body that evening, put a stop to any further examination.

"I should have been happy, gentlemen, if I had been able to have given you a more particular and accurate description of this very singular case, but the above-mentioned circumstances forbade."

About a half century later, Williamson of London, in 1841 and Dawosky in Germany in the year following, mentioned the projectile character of the vomiting and each reported a case with autopsy findings. In 1888, Hirschsprung awakened the modern interest in pyloric obstruction with his discussion of the clinical symptoms and presentation of two necropsy specimens before the German Pediatric Society. Following this, Ibrahim collected over four hundred cases about twenty years later. In 1896, Finklestein first called attention to the palpable tumor. The first surgical procedure was performed by Cordua in 1893 and was a jejunostomy. In 1898, Willey of New York and Stern in Germany each reported a case of gastroenterostomy and this operation continued to be done for a number of years. In 1907, Fredet performed the submucous pyloroplasty by means of a linear incision down to the mucosa and suturing the longitudinal wound into a transverse one. Rammstedt, in Germany, in 1912, advised omitting the transverse suturing and leaving the wound gaping.

As to statistical data on the incidence of the condition, I can only cite the report of Hertz published in 1916, in which he states that 27 per cent of all children under one year show the condition. Walls, comparing appendicitis with pyloric obstruction, observed in a clinic of five thousand cases a year, less than five cases of acute appendicitis and thirty of pyloric obstruction, over a five-year period. There have been eight cases in the Portsmouth Hospital in the past five years.

A condition so common needs only mention of its cardinal symptoms: projectile vomiting, loss of weight, visible gastric peristalsis, with or without a palpable tumor, since the underlying pathology considered responsible for the symptoms is spasm of the pylorus with or without an accompanying hypertrophy. Also, the symptom of tumor may be so difficult to elicit, that failure to identify it ought not to militate against the diagnosis. In our small series of seven cases, the tumor was distinctly felt only twice. W. R. Meeker, quoting Strauss, states that "he has felt it in only twenty-five per cent of his cases and attaches no significance to it". In his own six operative cases, it was definitely

found in two. These babies so afflicted are always constipated and the x-ray if employed will show evidence of obstruction. At the Children's Hospital in Boston, roentgenology is rarely done because it is not considered necessary, and it is not desirable that the stomach be full of bismuth at the time of operation. These cases, by the way, are all treated surgically. Recently the observation of the cold extremities has been suggested in addition to the above symptomatology.

For years, a great source of argument was the question as to whether the hypertrophy preceded the spasm or the spasm caused the hypertrophy. The pathogenesis, discussed at considerable length in the literature, has, at least until quite recently, remained rather obscure. Numerous explanations, all unsatisfactory, have been given for the spasm theory. Among these are the following: that the spasm followed by hypertrophy took place in utero as the stomach tried to rid itself of swallowed amniotic fluid, hyperadrenalism in the mother, phimosis causing irritation and accounting for the condition occurring so much more frequently in males.

Thomson, in 1897, stated that pyloric stenosis is a functional disturbance of the nerves of the stomach and pylorus. Haas suggests a disturbance in the vegetative nervous system with hypertrophic pyloric stenosis, an advanced degree of pylorospasm, and the two the most marked features of a general hypertonicity. Stenosis of the pylorus has been produced experimentally in dogs by Elsesser and in rats by Hoelzel and DeCosta. The latter found that gastric retention occurred with low protein feeding. Autopsy findings: stomach large, pylorus markedly constricted, and when the digestive tract was filled with fixing fluid shortly after death, the pylorus acted as if it were spastic.

In various gastrointestinal studies, they had often injected formalin-Zenker solution into the intact stomach, either through the duodenum or the esophagus, and in rats that had been kept on diets that tended to produce gastric retention, the passage of the fixing fluid was often obstructed entirely at the pylorus, while in rats that had not been kept on such diets, the fluid passed the pylorus easily. A pyloric hypertrophy such as occurs in infants was, however, never seen.

The proponents of the tumor theory hold first, that there is a primary developmental hypertrophy of the pyloric ring and canal and that the reduction of the lumen of the canal by the thickened muscle causes the obstruction, and, secondly, that there is an incoordination between the pyloric sphincter and the muscle of the pylorus, and that failure of the sphincter to relax causes the resistance which leads to hypertrophy of the pylorus. Apropos of this, Alvarez says that there is no definite pyloric

ring of muscle, for the pyloric muscle is but the lower end of the thick layer surrounding the pars pylorica of the stomach.

According to Sauer, the persistence of hypertrophy months after spontaneous recovery and in a cited case of a man operated for ulcer after a gastroenterostomy for stenosis, and in whom the thickened pylorus was seen to be still present, proves that the hypertrophy is not dependent on the spasm. On the other hand that the clinical picture is dependent on the spasm whether accompanied by hypertrophy or not, seems to be borne out by the behavior of some of our cases, one of whom in particular did not vomit at all for four days and was discharged from the hospital only to return some days later vomiting as on his previous admission. Another, on whom a Ramstedt operation was done, began to vomit three weeks after the surgical treatment, which I am certain was complete, and showed visible gastric peristaltic waves with the vomiting of the projectile type continuing for about two weeks.

Many writers believe that the spasm involves not only the pyloric ring but the entire pyloric end of the stomach and even the whole of the stomach. Though no studies leading to the foregoing beliefs had included the nerves controlling this portion of the gastrointestinal tract Moore quotes Ellrich as stating that "the majority of writers attribute the disorder to an imbalance of the autonomic or involuntary nervous system, which of course consists of two divisions, the parasympathetics and the sympathetics, the functions of which are opposing."

Here, the physiopathologic views of Eric Prichard of London are of interest. He says "The pyloric sphincter does not obstruct the outflow of the stomach contents owing to organic stenosis—it stops it because the opening is actually occluded or slant and refuses to relax. The normal resting condition of all sphincters is one of tonus, in other words, they are closed. The whole question of the innervation of the sphincter mechanism is very obscure but it is agreed on all sides that when the sphincter is at rest it is closed and when it is in its active phase, it is open. But the exact manner in which the nervous system, or the pneumogastric nerve, controls the action of opening, is still in doubt. In the case of the pylorus, it appears that the peristaltic wave, controlled and initiated by the vagus, passes along the pyloric end of the stomach and finally terminates in relaxation of the sphincter proper. It commences in the muscles of the antrum and ends in an active phase of relaxation of the pyloric sphincter. The latter is a comparatively small structure, constituting an insignificant part of what is commonly known as the pyloric tumor in cases of hypertrophic pyloric stenosis."

With regard to the pyloric physiology, Gian turco of the Mayo Clinic reported in 1933 some results following experimental studies on the

pyloric mechanism in which he had outlined the two curvatures of the stomach, the pyloric ring and the contours of the duodenum, with lead shot placed under the visceral serosa. Then with roentgenograms he took records of every phase of gastric activity. He found that food leaves the stomach when the pylorus and the duodenum are relaxed at the same time, and that relaxation of the pylorus alone is not followed by the passage of food. Alvarez states that the pylorus is opened by a wave of relaxation that normally follows a wave of contraction, and material is pushed out by the next wave of contraction which follows at a distance of several centimeters. Food goes into the pylorus which is open much of the time but passes through only at intervals. Forces below evidently balance those above. The duodenum, if not stimulated and caused to contract actively will allow the stomach to empty.

As previously suggested, no cause for "the disturbance of the physiological function of the vegetative nervous system" had been developed so it remained for Moore, Plymate, Brodie Dennis and Hope, working in the Nutritional Research Laboratories of the University of Oregon Medical School upon problems connected with the effect on the young of inadequate maternal diets during pregnancy and lactation, to make some remarkable observations and to produce the disturbance experimentally in albino rats. Their research work concerned the effects of the lack of the vitamin B complex. Laboratory animals on diets containing two per cent yeast produced ten cases of pyloric obstruction together with hemorrhage of both the young and the mothers, and a high percentage of deaths with terminal paralysis. In percentage obstruction occurred in 12 per cent of the young of the first generation and in twenty two per cent of the young of the second generation. Changing the method to the giving of 2 of a gram of yeast daily excessive hemorrhage stopped and no cases of pyloric stenosis appeared. Brodie reporting on the above mentioned cases, states that at autopsy the stomach was distended to at least three times its normal size by tightly packed curd. The pylorus was tightly constricted but patent to the extent that a small probe could be passed with difficulty. In some cases, the pylorus appeared grossly hypertrophic. In the cases in which the condition was mild or was cured by atropine, polyneuritis was later superimposed upon the original condition. The pyloric obstruction is therefore considered as one manifestation of vitamin B deficiency with a resulting defective myelinogeny.

As to this last point, C. O. Prickett following his studies on the effect of a deficiency of vitamin B upon the central and peripheral nervous systems of the rat, thinks that the conclusions of these and other investigators as to myelin degeneration of the peripheral nerves may be in error due to the inadequacy of their methods.

of preparation (March). He found, however, definite changes in the central nervous system.

It has been suggested that the extent to which the findings on rats are transferable to man is something of a question. However, rats are omnivorous like man, both species develop lesions with inadequate diets.

The familial incidence of this condition though unexplained is nevertheless interesting. As previously mentioned, the case reported by Armstrong in 1777 was the third in the same family. Sauer speaks of two families in each of which there were three cases and twin boys in whom the disease was shown at autopsy. Finkelstein described four cases in one family and three cases in each of two other families. Caulfield noted two cases in successive generations. Roche reports the case of a boy, the sixth birth in a family, in which the fifth, also a boy, had pyloric stenosis.

Koplik ascribed the condition to a neurosis and in some cases, heredity. He had two cases in sisters whose husbands were brothers and sufferers from gastric neuroses. Both of these sisters had babies with pyloric spasm and stenosis.

With their experimental work in mind, Moore et al. ask whether or not this phase of the condition may be dependent upon the fact that food habits run through several generations. They also suggest the possibility that "a varying demand for the antineuritic vitamin may be the hereditary factor."

Ernberg in Stockholm suggests a hypothesis based on clinical observation. He noted the occasional admixture of blood in the vomitus observed in chocolate-brown streaks or the whole material of this color. There never was fresh blood or violent vomiting. The first symptoms set in suddenly—explained by a sudden irritation of the pylorus. He says that the rapidity of increase in the quantity of breast milk taken during the third to the sixth week makes demands on the unaccustomed stomach and pylorus and a small rupture of the pyloric mucous membrane is his conjecture. He has been unable to prove it histologically.

The trouble develops in males much more frequently than in females, the ratio being three or four to one. In seven of our cases, five were males and two females.

This is also said to be true in beriberi due to vitamin B deficiency and in polyneuritis occurring in animals and due to the same cause.

This mass of experimental evidence, though perplexing, forces the conclusion that any modern conception of the probable cause of pyloric stenosis, whether one believes it to be vitamin B deficiency or not, precludes the idea that all cases are surgical from the beginning.

T. H. Lanman and Patrick J. Mahoney in

February, 1933 published a report of four hundred and twenty-five cases operated by the Friedet-Rammstedt pyloromyotomy at the Children's Hospital in Boston where it is the treatment of choice. The mortality was 63 per cent with 104 per cent in the early cases, reduced to two per cent in the later group. Since this report, however, they have done considerably more than one hundred cases with no mortality. In this connection, Haas says: "The reason the Rammstedt operation is superior to any other operation that has been attempted is that it does the same thing as medical treatment by severing the nerves through which the reflexes are produced. If the nerves are not severed, the results are incomplete after resection of the tumor."

That atropine affects the termination of the nerves and not muscles, accords well with the assumption that the spasm is produced as a reflex.

The usual treatment in this country has been atropine and thick cereal feeding and refeeding. Recently phenobarbital has replaced atropine to some extent. H. L. Moore says, "I believe the effects of this drug prove that the condition is also cerebral in origin and the phenobarbital inhibits emetic impulses carried by the gastric nerves to the vomiting center." Moore's cases average a week to ten days in the hospital, a shorter time than with surgery.

In addition, these babies must be given salt solution twice daily by hypodermoclysis and this must be done regardless of the control of vomiting.

J. B. Sidbury in 1927 described the good results in severe malnutrition, of blood transfusion in infancy. Blood increases food tolerance and resistance to infection. It has a food value and a vitamin content. It would seem, therefore, to be a most valuable addition to the usual treatment of these infants. It is obtained from the father—typing is not necessary—and it is given subcutaneously on the sides of the abdomen in amounts of 25 to 50 cc per kilogram of body weight.

The addition of vitamin B to the diet gave no striking results over those reported similarly treated by others but without the addition of vitamin B. However, in the presence of cold extremities, subnormal temperature and poor appetite, it is invaluable.

No one of the mothers to whom we have given brewer's yeast in the past five years has had a baby who has had either pyloric stenosis or hemorrhage of the newborn.

In conclusion, I believe that with the present status of our knowledge concerning the problem, medical management should first be tried with the weight curve, determination of the amount of fecal matter in each twenty-four hours, the general condition of the patient, as stated by Sauer, the criteria for determining how long the treatment should be continued.

DISCUSSION

PRESIDENT LORD I will ask Dr. Benjamin P. Burpee of Manchester to open the discussion on Dr. McGill's paper on "Congenital Pyloric Obstruction."

DR. BURPEE Dr. McGill is to be congratulated on this paper for again bringing to our attention the fact that this is a condition that does occur not infrequently in early infancy and for stressing the fact that it is important that as early a diagnosis as possible should be made when the condition does arise, inasmuch as the treatment is always and completely surgical.

I believe that the history and symptoms of this condition are usually pretty clear and definite and that none of us will have much difficulty in the diagnosis if we will but remember that a sudden onset of vomiting at about the fourth week calls not for a tinkering with the infant's feeding but for a careful examination of the upper abdomen while the infant is taking its food to determine whether peristaltic waves are present.

I believe that the important points in diagnosis are three in number. First is the history. The onset is usually sudden. The mother can usually fix this onset almost to the hour that it began. This is between the third and fifth weeks. Vomittings beginning at birth are unlikely to be tumors although I have seen one case in which this did occur.

Secondly is the magnitude of the waves in differentiating pyloric tumor and gastrospasm or pylorospasm. I believe that when the waves are very definite and high often with more than one visible at a time, this is in favor of tumor. Peristaltic waves do occur in spasm but they are not so clear cut and definite.

The third point in diagnosis is differentiating tumor and spasm in doubtful cases is in the feeding of a thick cereal formula. If the infant persists in vomiting when this is fed the chances are overwhelmingly in favor of a tumor being present. Cases of spasm do not vomit thick cereal to any appreciable extent.

It has been my experience that feeling the tumor is difficult. As an interne on a service on which there was always at least one pyloric stenosis this did not seem so difficult. Of late I have not found it easy to feel the tumor. It is undoubtedly difficult, due to the location, but probably the answer is that it requires considerable time and patience in palpation.

Concerning the use of the x-ray in diagnosis this has always seemed to me to be an unnecessary procedure. It tells us nothing more than that we have stasis which we already knew.

In the after-care preference is decidedly for whey and glucose. This provides an easily assimilated non-card forming food. Reporting sixteen cases operated by Dr. David W. Parker it is of interest that the last six cases fed on whey and glucose with no mortality have shown an average gain of eleven ounces over a ten-day postoperative period. The previous ten cases, fed on various formulas mostly low fat mixtures and lacto acid milk had a mortality of thirty per cent and over a corresponding ten-day postoperative period those that lived showed an average gain of only five ounces.

PRESIDENT LORD I will ask Dr. E. L. Levine of Portsmouth to continue the discussion on this paper.

DR. E. L. LEVINE, *Mr. President and Gentlemen of the New Hampshire Medical Society*—I was greatly impressed with the report of the work done at the Children's Hospital particularly the mortality rate which is very commendable.

However a report which was made in 1934 in the *British Medical Journal* by Dr. Wallace of the Edinburgh Child Hospital in Scotland is very illuminating to the extent that it goes to prove that surgery is not always the method of choice over medical treatment. Their mortality rate in that clinic is reported to be 24.8 per cent, which is practically twenty-five per cent. In other words one out of every four patients died of some complication or another.

Perhaps outside of Boston and in other clinics, the mortality rates are much higher than reported at the Children's Hospital. This is very interesting because the pediatrician and the profession at large always think of the surgical treatment and do not attempt medical relief consistent with the safety of the patient.

PRESIDENT LORD Discussion is now open to guests and members of the Society.

DR. DAVID W. PARKER, *Mr. President Ladies and Gentlemen*—I think that this group of men should be congratulated for their exposition of this very important and timely subject. There is no question in my mind but that this condition occurs very much more frequently than is recognized and that many of these cases are carried along as feeding cases until the disease or condition is far advanced and consequently the mortality raised.

This may be a bold statement, and I don't want you to take it in the way of criticism but I don't think there is any particular reason why these cases should be missed for any considerable length of time.

As has been brought out, the symptomatology the history etc. is quite striking and quite definite. It isn't necessary to diagnose a tumor in order to make a definite diagnosis. If I have peristaltic waves vomiting which has come on suddenly more or less and in a previously apparently healthy newborn and the ejection of thick cereal gruel, with loss of weight, etc. I think it is very strongly diagnostic. My feeling is that very little time should be wasted on these cases in fooling around with changing foods and trying to get them as feeding cases. If they eject thick cereals for any considerable time, for a period of days I am firmly convinced that we have a tumor at the pylorus and it should be investigated.

X-rays as Dr. Burpee said are absolute nonsense they tell you nothing and are unnecessary.

It was rather interesting that Dr. McGill spoke of the familial instance. We had three cases in one family.

Now the operation of choice is the Ramstedt operation without question. From time to time there have been articles published on modifications of the Ramstedt operation. It is like putting the momentum up over the raw surface making transverse cut at one end of your incision, that, to obviate the danger of getting into the duodenum. I originally might state that there is a distinct danger of that, because this tumor mass runs off very gradually into almost nothing as you might say into the mucous membrane of the duodenum and in spreading your incision into the pylorus great care must be exercised not to open the duodenum. It can be repaired but it is not nice. It is a nuisance.

Now the Ramstedt should be done very quickly and there I think, is one of the important things. These children are babies, are dehydrated and are poor surgical risks and it is necessary to get in and get out just as quickly as possible consistent with good work so the less technical procedure that is carried out, the better. A small incision in the right upper quadrant over the left of the liver identifies the tumor masses with your finger lift it into

the wound, incise, spread it with the forceps Close it, and do it in five minutes

There is another thing These operations, although possibly they are emergency in some cases, should be treated as actual emergencies, that is, they should be operated on within five minutes of coming into the hospital These children are dehydrated, almost mummified in the late cases, and if you are going to keep your mortality rate down, it is absolutely necessary to get fluid in Fill them up with salt solution before putting them onto the table I think that is one of the most important things connected with the operation Don't forget that

On transfusions, we have had no experience with them at all at the Balch, and so I don't think we would have saved any of our babies on that score

Another important thing is the after-care Dr Burpee has given you statistics about the last sixteen cases fed on whey and carbohydrates, they used to say that the salvation of these children lay in the feeding of breast milk, and I think that is true, but I don't think it is so true as it was before we got on to this whey feeding

DR WINOGRAD *Mr President*—I wish to congratulate the speakers on their very complete and excellent papers, especially Dr Burpee, for bringing out so clearly the difference between the two types of cases Pylorospasm might be called a local picture of a general syndrome, the hypertonic baby There are various degrees of hypertonicity When we have a very hypertonic baby, we begin to wonder whether we have a pyloric stenosis I feel, as they do at the Children's Hospital, that one must feel the tumor before operating for, after all operations are not the methods of choice, but especially in children the method of last resort When a child is brought in to the office, it is very easy to tell a hypertonic baby, one sees a wiry infant with spastic, crossed legs, the so-called colicky baby of a nervous mother Here heredity comes in, for the mother, also, is a high strung person in most cases

In those cases, great care, medically, may do much. In a small town like Nashua, with about 30,000 population, in the past two years, there have been only two infants operated upon for pyloric stenosis Those children, in contrast to the hypertonic baby, were not hypertonic at all A definite tumor was felt in both cases Of course, in many cases there may be a combination of both All the hypertonic cases have responded either with atropine or thick cereal I might say that with atropine one must be courageous and at the same time cautious in its use Some babies seem to have overdosage with a half drop of a one thousandth solution They will become red and show dilation of the pupils Other infants may stand twice or three times the adult dose, and may respond to large doses Then, if that doesn't work, the thick cereal feeding usually will.

Some cases may be very bad and may show, as Dr Burpee brought out, not the real wave that we see in the pyloric stenosis, but the suggestion of waves I remember the case of a baby four months old the child weighed eight pounds at birth, and at four months, it weighed six pounds The vomiting was projectile in character, but that infant did gain, with the use of atropine and milk, and is today a fine child

I might say this, too, that the simple things in infant feeding are much more important sometimes than the gross things and are often overlooked because of their simplicity For example, many babies find it difficult to digest fat, there may be severe vomiting with a great deal of cream Skimming

the milk might do more, sometimes, than some of the more radical procedures

PRESIDENT LORD Is there any further discussion of this subject?

DR LOUIS C AGER My ideas on the subject of pyloric obstruction in infants are undoubtedly influenced by the fact that my knowledge of the condition goes back to the days when a posterior gastroenterostomy was the customary operation Naturally we waited a long time before undertaking a procedure which was followed by death in a large majority of cases

We ran through the gamut of feeding theories and when the thick gruel feeding was adopted we got very remarkable results in a goodly proportion of cases It was a troublesome and messy performance to shove the food down the infant's throat with a tongue depressor and we had difficulty in many instances in having the parents continue the method long enough for safety Statistics proved pretty conclusively that breastfed infants were fully as subject to the condition as bottle babies and it was generally believed too high fat in the breast milk was a causative factor, producing hyperacidity Hyperacidity and cyclic vomiting were the buggaboes of pediatricians in those days Perhaps the vitamins have corrected all that.

The Rammstedt operation was of course a tremendous step in advance but we had learned in the meantime that a very large proportion of the cases could be successfully treated without operation My belief that the primary condition is spasm and that the actual stenosis is a secondary hypertrophy due to spasm is merely strengthened by the statement made here today that the tumor usually shows up at about the fourth week The very definite symptoms of obstruction almost invariably appear in the second week after birth I agree absolutely with the previous speaker that, if the infant lives to the fourth week, operation is indicated, and I would go farther and say that in most cases surgical intervention should be made before that time

DR FRED B LUND We have just heard a little conservatism preached I think the definition of conservatism is really the kind of conservatism that saves life, and not the kind that avoids a simple and life-saving operation

After you have seen these cases, with a certain onset of symptoms in previously healthy children, if you wait until you can feel a tumor, you usually wait too long Children change so quickly, so much more quickly than adults They are growing fast, and they go off just as fast as they come on The idea of waiting until you have tried every possible thing strikes me as the very best way to get a high mortality, and the statistics that have been shown here today demonstrate that to be bold, if you can call it being bold, is really being careful, therefore, an early operation is really being careful

DR FRANK N ROGERS There is a danger point, beyond which it is not advisable to go Most doctors who are experienced with this condition will get this child into the hospital and operated upon as soon as possible

An economic point is this In large hospitals, there is a tendency to operate as soon as possible and send them home in about three weeks to avoid cross infections

The cases that we have had that I have observed in the city have been cases which were so early that it was impossible to feel the tumor on most of them

One case that Dr Parker mentioned that I had to do with had three in one family, they were all breast fed, and the mother carried the baby around

nader her arm and fed it almost constantly. When the baby entered the hospital it would have made a gain if all things had been equal. But the vomiting was persistent and characteristic of hypertrophic pyloric stenosis and after going over the case thoroughly in the hospital and giving it sufficient time the case was operated upon and a sizahia tumor was found. The baby was discharged in three weeks, on the road to recovery. And that has been the story as time has gone on.

Men are more alert in making these diagnoses today and I think that we are getting into the hospitals better risks than we ever had before.

I think the objection to surgery in the past has been that the cases were such poor risks when they entered the hospitals that the surgeon was almost discouraged from the start.

DR. HERBERT L. TAYLOR. Cases of pyloric stenosis in children. I think render no difficulty in the matter of diagnosis and the treatment of course should be early and it should be prompt.

Cases of pyloric stenosis of course present two kinds. They present a hypertrophic kind in which the circulatory muscular fibres are greatly enlarged and increased in number and you also have the form of pyloric stenosis in which it is simply a spasm of the pylorus. In that instance it is supposed to be due to some defect of the vagus nerve in that region.

THE AMERICAN PUBLIC HEALTH ASSOCIATION CONVENTION

Leaders of public health and preventive medicine from every state of the union and from several foreign countries are to be at hand for the sixty fourth annual convention of the American Public Health Association to be held in Milwaukee from October 7 to 10.

Workers in all fields of public health medical men, nurses, specialists in research and others in allied activities are to be among the 3,000 delegates expected at the convention.

Important developments of the year in preventive medicine in the extension of public health work and in the constant war on contagious disease will be unfolded at the gathering.

Simultaneous with the association's sessions ten other closely related organizations are to convene. They are the Association of Dairy Food and Drug Officials, American Association of School Physicians, Association of Women in Public Health, Conference of State Sanitary Engineers, Conference of State Laboratory Directors, Conference of Wisconsin Health Officers, State Registration Executives and State Directors of Public Health, Nursing International Society of Medical Officers of Health and National Committee of Health Council Executives.

Over 400 papers are to be presented dealing with such widely varied subjects as mental hygiene, diphtheria and scarlet fever immunization, poison in food, public sanitation, treatment of sewage and polluted waterways, public health engineering, planned milk control, laboratory studies with toxins and vaccines, tuberculosis, milk-borne disease, water purification, new methods in reporting vital statistics, industrial hygiene, food and nutrition.

Sessions of the association itself are to be divided among its ten constituent sections—health officers, laboratory vital statistics, public health engineering, industrial hygiene, food and nutrition, child

Of course, the treatment in the hypertrophic type is the Ramstedt operation which can be done very quickly under novocain and the results should be perfect in regard to the patient getting well if the case is done early.

The type of pyloric stenosis due to spasm often presents intermittency in the vomiting. They will vomit for a while, and then the child will go along apparently in perfect health again, and then start in vomiting. That is quite often the way with the type which is due to the spasm.

PRESIDENT LOAN. If there is no further discussion I will ask Dr. McGill to close the discussion on his paper.

DR. CHESTER F. MCGILL. The paper was not offered with the idea that vitamin B deficiency is necessarily the panacea. I daresay however that even only five per cent may in the future be treated successfully by medical management. The other twenty-five per cent will require, some time or another, the Ramstedt surgical operation.

I hoped that this paper would be provocative of greater interest on the part of all members of the Society particularly with a view to ascertaining if possible whatever information may turn out to be of value with regard to the mothers' diets. This, of course, concerns the obscure etiological factor particularly with regard to vitamin B deficiency.

hygiene, public health education, public health nursing and epidemiology.

There will be authoritative presentations on amebic dysentery, hemolytic streptococci, whooping cough, gonococcal infection, tuberculosis and undulant fever. Papers are to be presented on all trouble viruses and on prophylactic and therapeutic vaccination. Recent progress in biological products and research accomplishments of the year in the milk and dairy field will be on the program.

Among the outstanding physicians and health leaders who will speak at the convention are Dr. E. L. Bishop, President of the Association and Director of Health of the Tennessee Valley Authority; Dr. Walter H. Brown, President Elect of the Association and Professor of Hygiene at Stanford University in Palo Alto, Calif.; Dr. Herman N. Bundesen, President, Board of Health, Chicago; Dr. W. G. Campbell, Chief of the United States Food and Drug Administration, Washington, D. C.; Dr. A. J. Carlson, Professor of Physiology, University of Chicago; Dr. Haven Emerson, Professor of Public Health Practice, Columbia University; Dr. John A. Ferrell, Associate Director, International Health Division, Rockefeller Foundation, New York; Dr. Morris Fishbein, Editor, *Journal of the American Medical Association*; Dr. Grant Fleming, Professor of Public Health, McGill University, Montreal; Dr. Inga Galdston, Executive Secretary, Medical Information Bureau, New York; Dr. John P. Koehler, Milwaukee Health Commissioner; Dr. Carl S. Pederson, Chief in Research, Agricultural Experiment Station, Cornell University; and health commissioners of most large cities and research men on the staffs of foundations and major industries.

This congress is designed to appeal to members of the public health and medical professions alike. Headquarters are to be at the Milwaukee Auditorium. Scientific and educational exhibits will be staged. Entertainment and social events have also been planned.

MEDICAL PROGRESS

PROGRESS IN LARYNGOLOGY

BY LE ROY A. SCHALL, M.D.*

IONIZATION of the nasal mucous membrane has been given a new impetus by the work of Warwick and the enthusiastic attitude of the manufacturers of his electrical apparatus. Theoretically it is based upon the fact that the metallic solution placed in contact with the nasal mucous membrane, results in the precipitation of the proteins of the superficial cells. The method has been tried by Tobey¹, Alden², Hollender³, MacFailan⁴ and others. Tobey frankly states that it has not been tried in a sufficient number of cases, nor has sufficient time elapsed to judge the relief adequately, which may be but temporary, given 85.6 per cent of his patients.

Whether the effect of ionization is anything more than a cauterization of the nasal mucous membrane is questionable. It remained for Palmer⁵ to have the courage of his convictions and treat a group of thirty patients with vasomotor rhinitis by a local application of concentrated phenol. The immediate effect of this treatment was exactly that which was obtained by the ionization instrument of Warwick in that the mucous membrane showed a greyish, white discoloration followed by edema and obstruction with hypersecretion. Palmer had excellent cooperation from his patients, as they voluntarily permitted biopsies to be taken. The microscopic examination revealed that there was an increase in the connective tissue of the tunica propria with a diminution of the edema and vascularity. Of thirty cases treated by Palmer, twenty-four or 80 per cent showed definite improvement and twelve were free from symptoms for periods of from three to nine months.

McMahon⁶ approaches the subject of ionization from the pathologic point of view, by determining its effect on the nasal mucous membrane of dogs. He found that ionization is followed by a desquamation of the superficial epithelial cells, by an increased fibrosis of the connective tissue and by multiple abscess formation deep in the stroma. There was also a polymorphonuclear leukocytosis and an extravasation of red blood cells free in the tunica propria.

Fenton⁷ bluntly states that "ionization as such does not do anything more than damage the mucosal tissues of the sinuses."

The fact that hay fever is unknown in Japan, but that on American soil over three per cent of the Japanese population contract hay fever,

led to Hara's⁸ investigations. He found that the concentration of pollens in the air in Japan was much higher than that in Los Angeles, where he made his American studies. He also found all the Japanese pollens to be large, heavy and non-spiculated. He believes that the high humidity and abundant rainfall in Japan prevent dissemination of the light pollens which are usually associated as the causative factors of hay fever.

For many years mucous nasal polyps were described as myxomatous tumors. It is now generally conceded that they are merely exuberances of the nasal mucous membrane. Kern and Schenck⁹ believe that allergy is a constant factor in the etiology of all nasal mucous polyps. In their experiences all patients with mucous polyps have been found to have a general history of allergy, a family history of allergy, or positive skin tests, and usually all three.

TONSIL

The tonsil problem has been revived. For many years a paper on the subject of tonsils would have no place on a scientific program. The subject was thought to have been exhausted. A few years ago Kaiser startled the pediatric world by a publication of a large set of statistics from the school children of Rochester. The result of his figures showed that in his locality, the operation of tonsillectomy, does not in all cases, accomplish what the medical and lay public believed it would. In other words, he found that deep respiratory infections, namely, laryngitis, bronchitis and pneumonia occur more frequently in tonsillectomized children.

In a recent paper, Kaiser¹⁰ gives his findings following a reexamination of these children, ten years after operation. His statistics again show that the instance of bronchitis and pneumonia has not been lessened by the removal of the tonsils. He states, however, "My studies and end-results of tonsillectomy indicate that some physicians have underestimated the importance of the tonsils as a factor in disease. The outstanding problem with the physician is to discover a more accurate way of diagnosing diseased tonsils. There is no known therapeutic procedure that is of greater value to a child than the removal of diseased tonsils. The failures are largely due to the wrong diagnosis."

In the same symposium, Nissen¹¹ gives the result of his work, based principally on a survey of patients of the Robert B. Brigham Hospital. He found that of the arthritics, only 10

*Schall, LeRoy A. — Surgeon, Massachusetts Eye and Ear Infirmary. For record and address of author see This Week's Issue, page 555.

per cent had tonsillectomy performed before the onset of their arthritis. Of the 90 per cent that had retained their tonsils, with the onset of arthritis, only 45 per cent had tonsillectomy after the onset. In other words, this statistical study, showing 55 per cent of a group of arthritics, having tonsils intact for many years after the beginning of their arthritis, should answer the accusation as to the wholesale removal of tonsils in arthritis. Nissen very clearly brings out the fact that there should be a relationship between the focal and systemic infection before operation is advised and that after an operation is decided upon, the proper time for this procedure is when, not only the tonsillitis but the arthritis is in the state of absolute quiescence. Under no circumstances should an operative procedure be undertaken if the patient's disease does not reach a period of quiescence with measurable improvement.

Mullin¹² also pleads for a very thorough study of the patient before deciding that a disease is due to focal infection. He says, "I can only reiterate the caution and advice not to operate at random on a patient with focal infection and let the failure to obtain results tell you that his case needed more study. First, do everything else that might help and then, after time and careful study, resort to surgical removal only if there are definite indications. I wish also to emphasize the fact that care must be taken in training specialists so that they become doctors and diagnosticians first and surgeons after wards, that they do not hold out a tonsil and adenoid operation as a panacea for all ills and perform this operation indiscriminately without due and weighty consideration."

This is exactly the same attitude taken by Coates¹³ who very properly says, "It is usually possible for the painstaking laryngologist to determine the presence or probably absence of chronic sepsis of the tonsil. Where the tonsil is very definitely diseased, its removal for prophylactic reasons will often give striking results. When the tonsil is removed on mere suspicion, or after hasty and inadequate examination the guess may as well be wrong as right. When the septic tonsil is discovered in association with some systemic disorder, the diagnosis of tonsillar infection as the cause of this disorder can only be satisfactorily arrived at after meticulous study and consultation on the part of the laryngologist with the attending pediatrician, internist or surgeon."

Newhart and his co-workers¹⁴ have been studying the question of tonsillectomy in the tuberculous. Of 324 tonsillectomies in tuberculous patients, only one operative case, prior to 1926 showed an unfavorable course clinically. They believe that this high percentage of favorable results can be obtained only by a very careful selection of patients and that the operation must be guarded by a very careful technique and by

following a very carefully planned program for after care.

Schall¹⁵ analyzes a group of 230 cases of cancer involving the tonsil. The outstanding fact is that the majority of these patients endured their symptoms for from three to six months before consulting a physician. As a result of this analysis, it may be said that surgery has no place in malignant disease of the tonsil. The most encouraging results are obtained by radium implantation in conjunction with external radiation.

THE COMMON COLD

The common cold has continued to be a subject of study. Most investigators believe that the mucous coat which lines the nose plays an important part in the prevention of infection. Lucas and Douglas¹⁶ believe that the normal mucous coat is composed of two layers, an inner one of fluid, fluctuated by the cilia and an outer layer of mucus which carries away debris and foreign particles. The inner layer flows with the vibrating of the cilia against the under surface of the inner layer. Therefore, they believe that the rate of flow of mucus cannot be used as a reliable measure of the ciliary movement.

It is Proetz's¹⁷ opinion that where this mucous sheet is broken by a change in the surface epithelium, that bacteria can penetrate into the mucous membrane at these areas.

Hilding¹⁸ found that these changed areas of epithelium are sterile and it is his opinion that a powerful bacterial enzyme, which he has designated as "lysozyme", acts as a protective agent.

It is suggested by Negus¹⁹ that it is the changes of pH which paralyze the cilia and not the action of bacterial toxemias.

Tweedie²⁰ has studied the pH reaction of the nasal secretion by a colorimetric method and his findings suggest that the mucus of the normal nose can control pathogenic bacteria. It is not until the reaction becomes disturbed that the pathologic bacteria can retain a footing. However, Hilding¹⁸ found that pH was but little disturbed by pathologic conditions.

SINUSITIS

American laryngologists are quoted freely by Tilley²¹ in his Semon Lecture on nasal sinuses. He accepts Schall's histopathologic classification of sinus disease but adds an additional type, one in which bone changes have taken place. In discussing the operative treatment of chronic maxillary sinusitis he advocates the Caldwell-Luc operation for all cases except for those of the simple edematous type.

In Goodyear's²² experience, the intranasal operation in which a large opening is made beneath the inferior turbinate and the antrum packed with iodoform gauze which is left for three to nine days, produced as satisfactory results as the external operation.

Stevenson²³ reports seven cases of infection of the maxillary sinus in which fungus forms were found in the pus recovered from these sinuses. These fungus forms closely resembled those of *mucor histoides*. Four of the cases classed as chronic sinusitis had recurrent infections, while under observation, and in two of these cases fungus forms were also found in infections recurring after some months. The findings indicated that fungi were present as active agents, rather than as saprophytes.

From an analysis of his postoperative results, Hill²⁴ theorizes as to the causes of failure in a certain percentage of sphenoid operations. Most of the older authorities considered the intranasal approach quite satisfactory. There is, however, a growing conviction that the external approach to the ethmoid-sphenoid is not only the safest, but that more thorough surgery can be done. Even with external surgery, subsequent contraction of the operative opening may occur following sphenoidectomy and nullify the effect of the operation, even after complete removal of the anterior wall, including the pars ethmoidalis.

PHARYNX

Kully²⁵ classifies cysts of the nasopharynx as (1) cysts of the mucous glands, the true retention cyst, (2) retention cysts of the pharyngeal bursa, described by von Luschka, Thornwaldt and others, (3) degenerative cysts, representing vacuolization of the germ centers with subsequent cyst formation and (4) bronchiogenic cysts, situated in the lateral wall of the nasopharynx beneath the ostium of the eustachian tube. The symptoms are postnasal discharge, posterior cervical adenitis, occipital headache, otalgia and unexplained fever. Kully pleads for a more careful and thorough examination of the postnasal space.

Mattick and Thibaudeau²⁶ found but nineteen plasma cell tumors of the upper air passages in the literature. They report their case of plasma cell tumor occurring simultaneously in the nasopharynx and hypopharynx. These tumors display characteristics ranging from inflammation to malignancy. Very few show lymphnode involvement of recurrence after removal.

Pollock²⁷ reports two cases of plasmacytoma from the Massachusetts Eye and Ear Infirmary. He emphasizes the fact that they must be differentiated from multiple myeloma which can be readily done by careful roentgen examination of the skeletal system.

LARYNX

Keinan and Schugt²⁸ discuss abscesses of the larynx. The symptoms are pain low in the throat, hoarseness and dyspnea. Local examination shows an obliteration and bulging of the pyriform sinus. The operation proposed and

carried out on eight cases by these authors is an external exposure of the thyroid cartilage with a trephine through the cartilage to reach the abscess.

Both Wilkinson²⁹ and Tucker³⁰ report a case of congenital web of the larynx.

An isolated amyloid tumor of the larynx without any demonstrable underlying local disease or general amyloid disease was reported by Kramer and Som³¹.

In the past year many papers have appeared on the treatment of cancer of the larynx. An increasing number of radiologists are reporting their results by Coutard's fractional method of treatment and laryngologists summarize their cases treated by surgery. All laryngologists plead for early diagnosis. The outstanding symptom in malignant disease of the larynx is hoarseness, yet this symptom is ignored for months and even years. All writers agree that biopsy does not produce metastasis if surgical removal takes place soon after the biopsy.

Hirsch and Baum³² believe that in intrinsic laryngeal cancer, clinical cures can be obtained by roentgen ray treatment. In such cases surgery gives equally good results, but with a lesser degree of conservation of function and with an average operative mortality of about 15 per cent. In extrinsic cases, the prognosis is usually unfavorable, owing to the tendency to rapid spread and metastatic glandular involvement. In this group, surgery gives a high mortality and offers no assurance of cure. Roentgen therapy may produce a clinical cure in this group with cervical involvement, or if the case is hopelessly advanced, it may offer palliation, comfort and prolongation of life.

Clerf³³ in fifty-eight patients with cancer of the larynx treated by laryngofissure had five deaths from postoperative complications. Thirty-five of these patients, three years after operation, have been traced and are free from recurrence.

Jackson³⁴ reports on seventy-five patients treated by laryngofissure with 82 per cent alive and well for periods from five to twenty-one years.

Tucker³⁵ reviews 200 consecutive cases of cancer of the larynx. In fifty-eight of the cases laryngofissure was performed, in thirty-one, laryngectomy and in fifty-four cases x-ray and radium were used. Only three of these fifty-four cases are alive after three years.

Another review of cancer of the larynx is by Beck and Guttman³⁶ who summarize their results with 500 cases. Laryngofissure gave a cure in 80 per cent and laryngectomy in 59 per cent, at the end of five years.

Eguen³⁷ also writes a very good paper on cancer of the larynx, reviewing the symptoms

and urging early examination of the larynx in each case of hoarseness.

The effect of radium on the laryngeal cartilages has been the subject of investigation by Arbnöckle.¹¹ His study must be regarded as a preliminary report, as the amount of radium used was so small and the distance from the cartilage so great that proper evaluation of the effects of radium cannot be made.

Nelson and Hirsch¹² warn radiologists that they should safeguard their patients against radiation injuries, especially when sensitive tissues, such as the neck, are being treated. They present an autopsy report of radiation reaction with necrosis of laryngeal structures following radiation of the larynx.

In view of these surgical results laryngologists are loath to try radiation on operable cancer of the larynx. Radiologists are treating only those patients who refuse surgery, therefore a just comparison cannot be made until a sufficient number of cases have been treated and sufficient time has elapsed to evaluate the end results properly.

THE MORTALITY RATE

According to precedent, the beginning and ending of each year give the highest mortality rates in the returns from eighty-six cities of the United States. These figures are fairly representative of averages throughout the country.

Beginning with January 1935 the average rate in these cities has dropped from 13.2 per thousand of the population to 9.3 in the first week of September. This decline has been very close to that of the

preceding year except for a brief rise in the last week of July 1934 when it reached 12.2 but subsided quickly to 9.3 the last of August which is the same figure as that for the present year.

If the usual trend takes place, the mortality rate will now rise steadily through September and October with a more rapid increase up to January 1936.

It will be interesting to note whether the slightly higher rates of the years before the depression are to be repeated or whether there will be a lowering of mortality rates in the years to come.

TRACY B MALLORY, M.D., *Editor*

CASE 21381

PRESENTATION OF CASE

A twenty-eight year old married American school-teacher entered complaining of exhaustion

During the two years before admission she felt very tired upon completing her day's work. During the past five months her fatigue increased and a faint dark red mottling appeared on her face. Two weeks before entry a similar mottling appeared on her neck and legs and an ecchymotic spot about five centimeters in diameter on the right thigh. One week before entry she developed a sore throat and a cough which later persisted and was associated with grayish-green, occasionally blood-streaked sputum. She had some bleeding from her gums and a slight nosebleed. Her last period started nine days before entry and was marked by profuse flow and clots. She had very severe pain during the first day.

Her mother, father and three siblings were living and well. There was no history of bleeding. She had always lived in Massachusetts. She had the usual childhood diseases and a tonsillectomy and adenoidectomy fourteen years before admission.

The past history is non-contributory.

Physical examination showed a well-developed and nourished woman lying in bed in no acute distress. Her gums were bleeding and some blood was exuding from the left nostril. There were purpuric blotches over the legs and arms. Examination of the heart, lungs, and abdomen was negative.

The temperature was 100.8°, the pulse 108. The respirations were 20.

Examination of the urine showed a specific gravity of 1.012 and a very slight trace of albumin. The blood showed a red cell count of 2,260,000, with a hemoglobin of 56 per cent. The white cell count was 18,800. A smear showed the absence of platelets. No differential count is recorded. There was no clot retraction in forty-eight hours.

A splenectomy was performed soon after admission. She had an uneventful convalescence and was discharged approximately three weeks after admission. The last blood smear showed an increase in the number of platelets but was still within the limits of low normal.

CLINICAL DISCUSSION

DR BETH VINCENT Probably if they had taken the bleeding time on this patient it would have been delayed. I dare say it was done by Dr Reynolds before she entered the hospital. There were one or two features of this case that were not so favorable as might be inferred from the history as given in this report. Before the patient came to the hospital she had more bleeding than is indicated in this history, because splenectomy was considered before she got to the hospital. Then the note on the physical examination says "a well-developed and nourished woman lying in bed in no acute distress." That hardly paints the picture. She came in at six o'clock. I was talking to the husband down stairs and was summoned to the eighth floor. She was lying on her side and blood was pouring out of the left nostril, so much so that while we planned to take the spleen out the next day we had to alter our procedure, pack the nostril, transfuse the patient and do the splenectomy that morning.

This is a case of thrombopenic purpura. It is reported that the mortality is higher if you take the spleen out during the attack of hemorrhage. That is true, but transfusion combined with splenectomy is the most effective procedure to control the bleeding. Therefore, the more acute the bleeding the more acute the necessity of operation in spite of the risk, but at the same time if you could be certain they would survive the bleeding you would be glad to postpone the operation until a quiescent period. It is like an appendix, if you avoid the operation in a very acute attack. There is one factor in the blood picture that Dr Reynolds can comment on that is a little unusual.

DR GEORGE P REYNOLDS Certain things in the history are worth going over because the history as presented is not accurate. In the first place she had been flowing for twenty-one days when she was admitted instead of nine as the history states. Her menstrual history is worth going over in detail because it is significant, especially in view of later developments.

She started menstruating at thirteen, always had scanty periods, and had sometimes gone as long as four or five months without periods, particularly during trips to Europe or any changes in environment, but also she had often skipped periods at home. She never had a profuse period prior to the present illness. The last period before the present illness was distinctly scanty. The September period started twenty-one days before admission, and while it had never been really profuse as judged by normal standards, she flowed more each day than was customary for her.

For two months prior to operation she had noticed easy bruising, and had had frequent though not severe nosebleeds. Moreover, she

had had a little, constant oozing from her gums during this period which is of some significance since she had never had it before.

There are also certain other factors in the history that are worthy of our consideration. In the first place throughout life she had tended to be a very healthy person and was very active and rather high strung. For two years prior to the present illness she had been working extremely hard and was rather tired every night but in evaluating the amount she did this fatigue did not seem to be inconsistent with the degree of activity. During the last three or four months before admission, however, she had become abnormally fatigued, although doing less than usual. Throughout life she tended to be obese and periodically had gone on very extreme dietary restrictions. We do not know the cause of this disease, but the more I see of blood dyscrasias, the more I wonder if semi starvation over a period of weeks does not do something to the bone marrow. This individual had frequently lived for days, or even weeks, on nothing but orange juice or a similar dietary insufficiency. Moreover, her diet for the last two years was inadequate in protein, although all of her extreme dietary restriction was before that time. She had usually taken one helping of meat a day, but because she thought meat was fattening, and moreover did not like it, the amount was extremely small. That is, of course, insignificant in an anemia history, but I do not know if it is in this disease. There was no past history of abnormal blood loss.

When I first saw her two weeks before admission the red blood cell count was 3,800,000, the bleeding time was normal and there was no clot retraction in forty-eight hours. The clotting time, however, was not very much prolonged. The platelet count was recorded as 260,000 but I think we are often fooled by platelet counts which are at best inaccurate. The smear that I saw had very few platelets, approximately one to each high power field and I think that this is a more accurate estimation of her platelets than the count. As Dr. Vincent said we do not like to operate on these cases during the acute stage. At that time her flow seemed to be decreasing. The bleeding from the gums was minimal, and there were no nosebleeds. We therefore felt justified in trying other measures before suggesting operation. We first gave her a well rounded diet with plenty of protein, including large amounts of whole liver. Occasionally even in fairly severe thrombopenic purpura whole liver has proved to be effective especially when there has been an antecedent history of dietary deficiency. In this case it had no effect.

The next thing we tried was transfusion. Looking back I think that possibly we might have anticipated the emergency a little earlier

by the fact that transfusions did not have any appreciable effect. I think also we were swayed somewhat by the fact that there was very little bleeding other than menstrual, and we rather counted on the belief that menstrual bleeding in this disease is of less serious significance than other abnormal blood loss. She had four or five blood transfusions without any definite decrease in the menstrual flow.

She was then brought to the hospital, and as Dr. Vincent said, on admission it was obvious that the situation was quite serious and that an emergency operation was definitely indicated. Almost immediately after removal of the spleen all signs of bleeding stopped, not only the acute nasal hemorrhage and the oozing from the gums but also the menstrual flow. This is what usually happens but the interesting feature in this case is that it was twelve days after operation before she showed any increase in platelets. There was no bleeding, no purpura, but repeated blood smears showed only from one to three platelets per high power field. We do not know how to account for that. It is as far as I know a unique situation.

Just a word as to the prognosis which we felt justified in making at that time. Simply because she stopped bleeding her immediate prognosis was thought to be good. But at operation there was some evidence of cirrhosis in the liver which makes our prognosis a little more guarded than in the ordinary case.

It so happens that I saw her the day before yesterday when she came in because of slightly excessive menstrual flow. Her blood examination at that time was as follows: red blood cell count 4,800,000, hemoglobin 105 per cent by the Sahli method, histological appearance of the cells normal, platelets estimated as normal or increased, white cell count 11,400. The differential count showed only 30 per cent polymorphonuclear cells, which Dr. Minot feels is not a good prognostic sign. In all previous counts both before and after operation she had at least 70 per cent polymorphonuclears.

She looked extremely well and I felt that her prolonged bleeding with this period was not in any way related to the blood situation. She was seen yesterday by a gynecologist who reported that the flowing had practically ceased, but that examination revealed an extremely small, immature uterus. A pelvic examination had been made at the beginning of the present illness and was reported as normal. I think if we had realized that the uterus was immature we might have paid more attention to the flowing and felt that it was more abnormal than we did. In thrombopenic purpura one should regard any evidence of bleeding with a good deal of apprehension, and one always hopes to postpone operation until the acute phase is over. In this case we were less apprehensive than the subsequent course proves we should have been because she looked so well and because the bleed-

ing was largely menstrual rather than from other parts of the body. If we had known that the reproductive organs were so immature we might have regarded the uterine bleeding as distinctly abnormal and have been a little more concerned.

PREOPERATIVE DIAGNOSIS

Thrombopenic purpura

PATHOLOGIC DIAGNOSIS

Hyperplasia of the spleen

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: This woman went through the very typical course of thrombopenic purpura with splenectomy. I do not believe Dr. Reynolds would want to guarantee that she would not have a recurrence of the disease, however. This is a disease that has aside from the multiple hemorrhages no anatomical picture. The spleens are not characteristic. They ordinarily show a rather marked degree of lymphoid hyperplasia but not necessarily. As far as I know, no one has ever recognized any diagnostic criteria by which the spleen of a case of purpura can be recognized microscopically, in contrast to hemolytic anemia where it is easy to recognize the situation. Likewise at autopsy, where it has been possible to study the bone marrow, nothing specific to the disease has been recognized. Even though there may be some diminution in megakaryocytes the findings again have been inconsistent. Cases do die from time to time and that is one definite reason for not putting off operation too long. I think the single most serious danger is that of cerebral hemorrhage which is by no means infrequent. We have four or five cases on record here with single or multiple cerebral hemorrhage as the immediate cause of death.

DR VINCENT: It is only fair to say that the cerebral hemorrhages have all taken place after the spleen was out.

CASE 21382

PRESENTATION OF CASE

A seven week old American male infant was admitted with a skin eruption of two weeks' duration.

The baby was apparently well at birth except for "sniffles" which persisted until admission. Two weeks before entry the mother noted a rash which began on the soles of the feet gradually involving the legs, thighs and face. The condition became progressively worse. In spite of the fact that the baby had never nursed very well because of the sniffles the mother believed that he had gained weight.

The father, two brothers and four sisters were living and well. When the mother was three months pregnant with the patient she had

a rash on the palms of her hands, soles of her feet, thighs, genitalia and scalp. At this time a great deal of her hair fell out and she also had a sore throat. The rash and sore throat persisted for about four months.

Physical examination showed a poorly nourished but fairly well-developed infant. There was a maculopapular type of rash over both extremities from the soles of the feet to the upper thighs. There was much scaling over the soles. Around the nose and mouth the skin was fissured and crusted with some oozing. There were numerous rhonchi and râles throughout both chests, especially in the left lower lobe, but no signs of consolidation. The liver was felt two fingerbreadths below the costal margin in the right midclavicular line. The spleen was just palpable. There was some swelling of epiphysis of both radii.

The temperature was 100.8°, the pulse 130. The respirations were 25.

Examination of the blood showed a red cell count of 2,550,000, with a hemoglobin of 40 per cent. The white cell count was 45,600. Hinton and Wassermann tests were strongly positive.

Immediately after admission the baby received 0.5 grams of neoarsphenamin intravenously with no immediate reaction except for a temperature rise to 104° the following day. On the third day he developed a stiff neck. The Kernigs were positive. No signs of pneumonia could be demonstrated but he had many râles throughout the chest. He rapidly failed and died that day.

DIFFERENTIAL DIAGNOSIS

DR RICHARD S. EUSTIS: When I first saw this history, long before I reached the end of it, I had a diagnosis which I think you all have by now. It is an unusually typical history of congenital syphilis, with infection of the mother probable early in pregnancy. She had a perfectly definite case of lues which was transmitted to the fetus. There is no mention of whether the baby was full term or premature. The birth weight is not given so we cannot even make a guess from that as to whether it was premature, although the phrase "well developed" in the description of the physical examination at least indicates that the infant was not very premature.

The physical examination is very characteristic,—the eruption on the extremities, the scaling of the soles of the feet, the fissures and crusting around the nose and mouth. There is no mention of the anus. There might have been condylomata present there, presumably not, or they would have been mentioned. The liver was apparently slightly enlarged although not much so, as it is usually palpable in a baby of this age. Presumably the infant had some interstitial hepatitis due to syphilis. He also presumably has had an osteochondritis of the epiph

ribs, the long bones, showing up particularly in the radii. That is a very characteristic finding. What shall we make of the rhonchi and rales in the lung? I very much doubt if at this age, seven weeks, we have what is described as a white pneumonia, a syphilitic pneumonia. It seems much more likely that it is an extension of the process around the nose and mouth reaching down to the larynx and the trachea and giving us originally a syphilitic tracheitis and then secondary infection and probably bronchopneumonia, although on examination they could not find the spot or spots of consolidation.

The child had a definite secondary anemia undoubtedly due to the syphilis. The high white cell count is probably a polynuclear leucocytosis and probably indicates acute infection. There is no differential count reported.

At admission we have a seven week old infant with an active congenital syphilis. A sick infant because he is described as poorly nourished. The treatment he was given was perfectly proper. The only thing to do was to start treatment at once. I do not know whether they tried to get a dark field examination of any secretions from the fissures around the mouth. That probably would have confirmed their diagnosis. But in a situation like this treatment should be started without waiting for a Wassermann test. The day following the injection of neosarsphenamin something happened to this infant. His temperature went up and shortly after the temperature went up he developed meningeal signs. The first thought that came to my mind was whether they were rash enough to give that injection into the longitudinal sinus. I regard that as a dangerous spot and I made inquiry about that and was told it went into the jugular so we cannot trace our meningeal symptoms to treatment that was meant for the longitudinal sinus and did not hit it. I do not think the injection of neosarsphenamin had anything to do with the rise in temperature, the meningeal symptoms and the death. I think it is much more likely that it is a torpid infection in an already sick infant with a secondary infection of the respiratory tract. There is no record of whether his respiratory rate went up at that time. That would help us to come to a conclusion. Meningeal signs occurring in the presence of an acute infection in an infant may mean meningitis, may mean otitis media, may mean "meningismus," and may mean of course, any kind of meningitis.

In trying to sum up this picture without any information as to the state of the baby's ears, as to the appearance of the spinal fluid, knowing merely that it was a syphilitic infant who died very shortly after admission with a high temperature and with some stiffness of the neck and Kernig, it seems to me that the simplest diagnosis to make one that will cover all the

signs that we have described, is a diagnosis of congenital syphilis and probable bronchopneumonia. With the information we have we cannot exclude otitis media, and we cannot exclude a meningitis.

DR. HAROLD L. HIGGINS. About twenty five per cent of congenital syphilitic babies have involvement of the central nervous system. We shall have to consider as a possible cause of death in this patient syphilis of the central nervous system, possibly syphilitic meningitis or syphilitic encephalitis.

Another very common cause of death in the syphilitic baby is respiratory obstruction the respiratory obstruction is obstruction of the nose. The child has a rhinitis with a thick and possibly bloody discharge. The baby of seven weeks does not know how to breathe through his mouth and will not do so except when he cries. With his nose stopped up he will have difficulty inspiring, and may show as much retraction of the chest as a child with laryngeal diphtheria, when there is obstructed breathing in a child with a heart damaged by the spirochetes, myocardial failure and death of the patient may result. The rales in the chest may have been transmitted from the nose rather than be emanating from the bronchi or alveoli.

The syphilitic baby is likely to be premature and may present a nutritional problem. It is quite important that the baby receive proper nourishment and as good a feeding as one can give, this is best accomplished through the breast milk. One problem that came up with this baby was the question of keeping it with the mother so that the mother would be able to nurse the baby.

The giving of the arsphenamin may have stirred up the syphilis, especially the cerebral syphilis as this rise in body temperature suggests. However, I still think that the treatment that was given the child was the correct treatment. One or two injections of neosarsphenamin given to a child like this will usually clear up the symptoms surprisingly. In a great many cases after a few days one may not recognize the child as sick. The rash disappears, the snuffles clear up and the patient seems very much better. I do not see how in this case we can decide on this data given whether the death was from cerebral syphilis with damage to vital cells in the brain.

DR. AUSTIN W. CHEEVER. I think the situation has been very well covered. I certainly think that there was ample evidence on which to make a diagnosis without waiting for blood tests and to start treatment immediately. I am inclined to believe that the death was a Herxheimer reaction but I cannot be at all sure. If so I do not think one should be disturbed about it because if the child was in such bad condition that one injection of neosarsphenamin would light up the Herxheimer seriously enough to cause death, in all probability if milder treat-

ment had been started, such as mercury, in the hope of preventing a Herxheimer reaction, the child would have grown rapidly worse from the syphilis and would probably have died from lack of sufficiently energetic treatment. The Herxheimer reaction in adults with late syphilis is something to be watched for and avoided if possible. But that is a different problem. With syphilis in the adult it is not so overwhelming as it usually is in babies. I feel this was a death from syphilis probably all the way through.

DR HIGGINS: Do you not think it is rather unusual that the symptoms of what we may call secondary syphilis appeared when the child was five weeks old instead of being present when the child was born?

DR CHEEVER: No, I do not. I rarely have seen any evidence younger than two or three weeks. The books give one the idea that the child is frequently born with early syphilis and has the wizened old man look, but I have seen only one or two. As you look back I think you have not seen very many. I think from two to three weeks is about the time these rashes start.

CLINICAL DIAGNOSIS

Congenital syphilis

DR RICHARD S. EUSTIS'S DIAGNOSES

Congenital syphilis
Bronchopneumonia
Meningitis?

ANATOMIC DIAGNOSES

Congenital syphilis
Bronchopneumonia

Luetic meningitis?

Cirrhosis of the liver, syphilitic

Fibrosis of the adrenal cortex

Septicemia, streptococcus hemolyticus

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: I think the post mortem can only answer a few questions, certainly not all the interesting ones in this case. There is no doubt that the child had congenital syphilis, of course. The most striking features at autopsy, confirming what was found on clinical examination, were the conditions of the liver which showed diffuse cirrhosis of the type that is found only in congenital syphilis, and a uniform fibrosis running throughout the lobules. The epiphyseal lines showed very slight changes. I would not be able to make a flat-footed diagnosis from them alone, but on the basis of the liver there can be no question that we are dealing with congenital syphilis. The autopsy was restricted and we did not examine the head. A postmortem lumbar puncture was done and that gave a fairly turbid fluid with some increase in lymphocytes. A Wassermann was done and was anticomplementary.

I do not know any way of making a post mortem diagnosis of a Herxheimer reaction. The child did have a fairly extensive bronchopneumonia, both upper lobes were consolidated and the sections look histologically like a perfectly ordinary bronchopneumonia of the secondary infectious type. The blood culture showed hemolytic streptococcus. It certainly was not a syphilitic pneumonia.

ACUTE LYMPHOCYTIC MENINGITIS

FIRST clearly described by Wallgren in children and by Viets and Watts in adults, a syndrome, variously called "aseptic", idiopathic, epidemic and acute lymphocytic meningitis has been thought by some to be a clinical entity in spite of its unknown etiology. The disease, self limited in character, with a mild lymphocytic formula in the cerebrospinal fluid showed many constant signs that suggests a single causative agent. Only recently, as the result of Armstrong's investigations in the laboratory of the National Institute of Health, United States Public Health Service, the probable etiology has been disclosed.

The cause of this malady is a filtrable virus, recovered by Armstrong and Lillie and reported by them in 1934. The disease has not only been developed in monkeys but protective antibodies have been found in the blood serum of recovered human cases, both by Armstrong and by Rivers and Scott.

It is therefore felt that the symptom com-

plex is a disease entity, that the etiology is a filtrable virus and that the term "aseptic", as used by Viets and Watts, ought, in the light of more recent knowledge, to be replaced by an other designation such as the one suggested by Armstrong, "acute lymphocytic choriomeningitis", or, more simply, "acute lymphocytic meningitis".

If the work of Armstrong and the co-workers is upheld, as it appears to be by the report of others, a new disease should be added to medicine. This suggestion, made first by Wallgren in 1926 and again by Viets and Watts in 1929 and 1934, is now made more certain by the finding of a filtrable virus as the etiological agent.

CANINE DAYS

ONE did not have to sense the heat or to read the reports of drowning and week-end motor casualties to realize that we have passed through another summer. A glance through our public prints told us that it was the silly season in newspaperdom. We know that that is the time of year when space-fillers are required, so we do not object to the trivial and banal notices that round out many a column. We pass over with a deprecatory smile accounts of "human icebergs" and their mock heroism in subjecting themselves to bizarre experiments although we frown a little when such publicity exploits are described as "aids to science". We wonder what specialty is practiced by the "special correspondents" who by cable would startle the world by telling us that the scientists assembled in Moscow have at last discovered that cretinism and some nervous disorders are due to dysfunction of the thyroid gland. Those uninformal readers who like this sort of mental pabulum are welcome to it.

Our objection is directed not against these cheap and stale items but against the avidity with which the agents of the large press services hunt out and report untried remedies and unproved medical theories. We object not because our complacency is disturbed but because

of the lamentable and tragic sequels of such stories

We remember with sorrow the despan that followed the highly exploited visit of a Berlin physician, who, a large advertising syndicate would have us believe, held in his notorious "turtle bacillus" a cure for tuberculous infections. We recall the renewed hopes of tuberculosis sufferers at this announcement, how they deserted their physicians, then sanatoria and health resorts, only to return poorer in pocket and in health, with hopes crushed and frequently with cold abscesses for full measure. It was an outrageous affair.

Only recently we read in our esteemed *New York Herald Tribune*⁶ an account with the arresting headline, "Cancer Arrest by New Liquid Product". It related how an Ontario physician had, from harmless tiny organisms, produced a preparation which arrested the development of "carcinoma cancer". We know of the wave of eagerness which must have swept over the ranks of cancer victims when they read this "news", we know of their rush to secure some of this precious "Enesol", and, unless all precedents fail, we can foresee the cruel disappointment which may await them. If they lost faith in the medical news of their daily newspaper we would applaud, but, instead, they lose faith in medical science.

Our reproach is not directed against the Canadian doctor who gave in to the insistence of newsmongers, although it is a human possibility, if not a modern human tendency, to resist high-pressure reporters and their cameramen. Our sympathy goes to him. Our resentment is directed against the large news-gathering associations that serve our newspapers, and against the editors who not only accept these premature reports but give them bold display in their sheets. There is the "Science News Service" which gives to those publishers who desire it reliable accounts of scientific progress, but these accounts are not sufficiently florid to satisfy the present-day craving for "hot" news. The New York Academy of Medicine offers the daily papers wise estimates of medical events and discoveries. In its conservative comment (by Doctor Goldstein) on Doctor Connell's reported cure, he sounded the warning that "bitter experience has taught us to accept all announcements of discoveries on the cause or cure of cancer with utmost caution". The *Herald-Tribune* in its caption "Academy of Medicine Here Calls Report Remarkable," omitted Doctor Goldstein's "if correct". It would have pulled their punch.

We have had previous occasion to inveigh against the unscrupulous newspaper advertisement of nostrums, and now, for the public's sake and in the interest of the practice of medicine, we beg for expert supervision over the stories

of medical affairs that go into our newspapers. We cannot rid our memories of the tragedies that have been caused by this cruel exploitation of alleged cures.

PHYSICIANS AND VITAL STATISTICS

To the physician in his practice, vital statistics seem remote, and since, in Massachusetts they are collated for the Commonwealth by the Secretary of State and not by the Commissioner of Public Health, they may appear almost irrelevant. He forgets that among other things they give a picture of what he is doing.

It may not be of general interest that last year one person died in each of the towns of Gosnold, Middlefield and Rowe or that even six were so recorded in Gill, but the charts which appear in the Annual Report should be studied not only by every physician, but by every person interested in the health of the people of the Commonwealth. There are shown graphically the rapid increase since 1930 of the number of deaths from heart disease and from cancer and from diabetes, a continuing upward swing in these figures. The appalling number of deaths from automobile accidents rose sharply in 1934. There is a little improvement in dealing with appendicitis, the mortality from which one would expect to find diminishing instead of increasing as it has in recent years. The figures for tuberculosis and for "infant mortality" are the most encouraging.

This statistical presentation is fascinating in spite of the well-known inaccuracy of the method because in the case of each group it makes insistent for the thoughtful physician the question "Why?" The multiplicity of challenges is a little disconcerting.

There are two obvious errors associated with the statistical method: errors of fact and errors of interpretation. Concerning errors of fact the Report says: "The chief element of error in mortality statistics lies in the inaccuracy of the statement of the cause of death as reported by the attending physician", and the mitigation of the severity of this condemnation follows: "who may not have been in a position to feel reasonably certain as to the nature of the terminal illness".

It is not that the physician has any intent to deceive. Too often he is unaware, in the nature of things, of the exact changes which have taken place in the body of his patient and his statement of the cause of death is an approximation toward a final diagnosis. It behooves every physician, in the interest of science, that pole star of practice, to use every effort to make his approximation as close as possible to the actual facts, and be not satisfied with merely meeting the minimum requirements under which a death certificate will be accepted by the town clerk.

THE COMMONHEALTH

TUBERCULOSIS

A VALUABLE ISSUE of the *Commonhealth* (Vol 22, No 1) the quarterly bulletin of the Massachusetts Department of Public Health is devoted to the subject of Tuberculosis and is made up of articles by eminent authorities on such subjects as Tuberculosis in the Practice of Medicine The Differential Diagnosis of Tuberculosis, The Diagnostic Dispensary, The Care of Tuberculosis, The Role of Surgery in Pulmonary Tuberculosis, Hospitalization of Tuberculosis in Massachusetts, Diet in the Home Treatment of Tuberculosis, Extra-Pulmonary Tuberculosis, Tuberculosis in Children, The School Tuberculosis Clinic Program, Chadwick Clinic Results Tuberculosis Case-Finding in Children of School Age, Summer Health Camps, Teaching the Etiology of Tuberculosis, Policies and Routines for a Tuberculosis Nursing Service and Social Work for the Tuberculosis Patient. An article by Dr. Alton S. Pope, Director of the Division of Tuberculosis, shows the decline in the death rate from pulmonary tuberculosis from approximately 460 for females and 324 for males in 1849 to approximately 40 for females and 60 for males in 1933.

Certain definite advances have been made in recent years in the attack on tuberculosis. In the treatment of the adult type of pulmonary tuberculosis, collapse therapy has become widely accepted and has been responsible for the saving of many lives, and the shortening of the course of the disease in innumerable instances. Our new conception of the distinction between primary tuberculosis as it occurs in the child in the non-sensitive individual, and reinfection giving rise to the adult type in the sensitized individual, either adult or child, has clarified the picture of the course of the disease and the part that allergy plays in that picture. We realize now that childhood tuberculosis, important as it is, is fundamentally a benign infection, but that, instead of immunizing the individual, as was formerly believed, it actually renders his tissues susceptible to the tubercle bacillus so that a reinfection will give rise to the adult type of phthisis.

In Massachusetts, particularly, a fundamental concept in tuberculosis control has been put into effect with the Ten Year Program of case-finding in the public schools of the state. In this ten years, just ended, 400,000 school children have been examined by tuberculin test and x-ray of reactors and the work will continue under the control of the regional sanatoria. In Massachusetts also, the tuberculosis summer health camp has reached its fullest development under the joint auspices of the tuberculosis associations and the county sanatoria, ever mindful of the doctrine that "a camp is as good as its follow up."

The treatment of tuberculosis must continue, but in prevention lies the way to its eradication, and prevention depends on case-finding and follow up.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

MUNRO DONALD A.B., M.D. Harvard University Medical School 1916 F.A.C.S. Assistant Professor of Neurological Surgery, Harvard Medical School Surgeon in charge of the Neurosurgical Service, Boston City Hospital, Boston. His subject is "The Treatment of Compound Fracture of the Skull" Page 551 Address 818 Harrison Avenue, Boston

BOWMAN, KARL M. A.B., M.D. University of California 1913 Assistant Physician, Bloomington Hospital 1915-1921 Chief Medical Officer, Boston Psychopathic Hospital 1921 Assistant Professor of Clinical Psychiatry, Boston University School of Medicine Special Instructor in Social Psychiatry, Simmons College School of Social Work Address 74 Fenwood Road Boston Mass. Associated with him is

HOWARD, PAUL M. B.A., M.D. University of Pennsylvania School of Medicine 1933 Intern, Methodist Episcopal Hospital Philadelphia, Pa., 1933-1934 Intern, Boston Psychopathic Hospital, 1934-1935 Intern, Neurological Service, Boston City Hospital, 1935 Address Boston City Hospital, Boston. Their subject is "Report of a Case of Lead Encephalitis Due to Tri Ethyl Lead" Page 559

BARDOUR, ELLEN H. Graduate, Simmons College School of Social Work Social Worker at Clinic for "Study of Growth Development of Normal Child," Harvard School of Public Health. Her subject is "Adjustments During Four Years of Patients Handicapped by Polio-myelitis" Page 563 Address 54 Hancock Street, Lexington, Mass.

MARRS GEORGE A. A.B., M.D. Harvard University Medical School 1928 Assistant in Surgery Massachusetts General Hospital Junior Visiting Surgeon, Chelsea Memorial Hospital Surgical Assistant, Huntington Memorial Hospital Assistant in Surgery, Tufts College Medical School, and the Cambridge Hospital. His subject is "A Method of Repair of Femoral Herniae by a Fascial Strip from the Aponeurosis of the External Oblique Muscle" Page 565 Address 198 Commonwealth Avenue, Boston.

THE ANEMIAS OF PREGNANCY

Thanks to the excellent work of Strauss, Castle and others, the hitherto vague subject of anemia in pregnancy has been clarified, its etiological factors ascertained and correlated, and the treatment made sure and simple. Recent studies have shown that a large percentage of pregnant women show a varying degree of anemia from no apparent cause, i.e., in the absence of hemorrhage, sepsis or chronic disease. These "anemias of pregnancy" are divided into two types. The hypochromic anemia (corresponding to simple secondary anemia) and the macrocytic anemia of pregnancy (corresponding to pernicious or Addisonian anemia). It should be noted here that this is not the true pernicious anemia and differs from it in the fact that it clears up after pregnancy is terminated and does not recur.

Hypochromic anemia has its etiology in several factors: (1) defective diet, principally a lack of sufficient iron; (2) disturbances in gastric secretion, i.e., a lowering or absence of free hydrochloric acid. This gastric inefficiency has been shown to occur in more than fifty per cent of all pregnant women. (3) Inasmuch as the fetus draws its blood-forming materials from the mother, this represents a "chronic blood loss" to the mother.

The blood picture in these cases is that of simple secondary anemia, the decrease in hemoglobin is greater than the decrease in the number of red blood cells. The patient shows varying symptoms: pallor, fatigue, edema, dyspnea, digestive disturbances, etc.

The administration of iron in the form of iron and ammonium citrate, ninety grains a day, or of ferrous sulphate, nine grains a day, will

cure this condition and restore the patient to normal health.

Macrocytic anemia of pregnancy is fortunately not so common. This is frequently referred to as the primary anemia of pregnancy. It has its etiology in similar factors: (1) Dietary insufficiency (principally a lack of animal protein [vitamins] B). (2) Gastric insufficiency or lack of a specific factor in the gastric secretion necessary for the formation of blood cells. Experiment has shown that both these factors are essential for normal hematopoiesis.

The blood picture in these cases is like that of pernicious anemia. The decrease in the number of red cells is greater, proportionately, than the decrease in hemoglobin content, giving a color index of +1. Macrocytes and microcytes abound. The symptoms are more severe, weakness, nausea, vomiting, diarrhea, sore tongue, etc.

Liver or liver extract by mouth or injection will cure these patients. Relapse does not occur. Inasmuch as these patients have the same deficiencies that cause hypochromic anemia, iron must be added to the treatment.

As a matter of prevention, the diets of pregnant mothers should be sufficiently rich in iron and animal protein. Small doses of iron in either of the forms mentioned should be given prophylactically to every patient.

MISCELLANY

DR. GEORGE BURGESS MAGRATH HAS RESIGNED

The resignation of Dr. George Burgess Magrath, for many years medical examiner of Suffolk County, has been announced.

Dr. Magrath has occupied an enviable position in the confidence of the medical profession and the courts not only in Massachusetts but throughout the country, for he has played a prominent part in the development of the Medical Examiner System in supplanting the old coroner practice.

His reputation for profound knowledge of the problems incident to homicide has led to his employment in many prominent trials. Like many eminent persons in public life, he has survived the opposition of those who on occasion have tried to prevent his reappointment. A long list of governors has continued Dr. Magrath in office, which is a tribute to his standing.

It is hoped that he will have the comfort and enjoyment of a serene release from the controversies of public life. The *Journal* congratulates Dr. Magrath on his honorable retirement.

APPOINTMENT OF DR. J. J. GOODWIN

Governor Curley nominated and the Council confirmed the reappointment of Dr. J. J. Goodwin to the position of Medical Examiner of the Fourth Worcester District.

A LECTURE BY DR. CHARLES F. WILINSKY

Dr. Charles F. Wilinsky, Deputy Health Commissioner of Boston and Director of the Beth Israel Hospital, lectured September 12 on "Public Health and Community Relations" at the Annual Institute

for Hospital Administrators being held in Chicago September 11-15, 1935. This Institute is sponsored by the American Hospital Association, the University of Chicago and the Chicago Hospital Association and is being conducted for the purpose of furthering the training of hospital superintendents.

DIAGNOSIS IN AN EPITAPH

BY FREDERICK C. WAITE

One finds unexpected novelties in the epitaphs of nineteenth century tombstones. Usually they have to do with the uncertainty of life and spiritual preparation for what follows. The epitaph here quoted, probably written by a physician, has a quite different purpose, that of medical advice to the living. The physician mentioned, Dr. Charles Knowlton (1800-1850), was a graduate of Dartmouth Medical College in 1824 and also received an honorary degree of doctor of medicine from Berkshire Medical Institution at Pittsfield, Massachusetts in 1827. He was a member of the Massachusetts Medical Society from 1844 and practiced at Ashfield, Massachusetts, some thirty-five miles from Pittsfield, for twenty-five years. In the cemetery at Ashfield today stands a stone with the following inscription:

Stephen Owen
son of Dr. C. Knowlton
died

Sept. 11, 1849
ae. 20 yrs. 10 mo. 12 d.

Reader, if your friend breathes too frequently, however mild the other symptoms, rest not easy under the fallacious idea that "It is nothing but a cold."

One may infer that this son was the victim of pneumonia, and that the epitaph aimed to prevent a similar catastrophe among his friends and neighbors. Since the father died five months after this son's death, it is possible that the epitaph was written by his surviving brother, Dr. Charles Lorenzo Knowlton (1824-1898), who attended at Berkshire Medical Institution in 1843-44 and graduated at Jefferson Medical College in 1845. He practiced for over fifty years, the greater part of this time at Northampton, Massachusetts. He was a member of the Massachusetts Medical Society from 1851.

OUTING AT THE WOLLASTON GOLF CLUB

A joint golf outing of the Quincy City Hospital Staff, the Norfolk South District Medical Society and the South Shore Dental Society was held at the Wollaston Golf Club on Wednesday, Sept. 4, 1935.

About forty of the combined group played golf under inclement conditions.

The outing was successful in a "get together" as the foursomes were arranged to include both medical and dental men.

nervous diseases. However in the latter chapter the author seeks to correlate these two subdivisions and by the use of photomicrographs and a few colored plates makes out an excellent and interesting case for the relationship between sinusitis and mental disease. The final chapter is devoted to a résumé of illustrative case histories, and there is an appendix describing the technique for preparation of gross and microscopic specimens. A long list of bibliographic references is appended.

The text is at times annoyingly replete with references to other authors, a feature which tends to break up both the author's and the reader's train of thought.

Studies from The Rockefeller Institute for Medical Research Reprints Volume 93 593 pp New York The Rockefeller Institute for Medical Research

In this volume the experimental studies of Webster and his associates on the St. Louis encephalitis virus are continued. There is the usual wide range of material from the fields of organic chemistry, chemical pharmacology, physical chemistry, and general physiology. From the department of the hospital there are several papers of interest. Page and others present further work in the field of hypertension, and Page also has a report on the prevention of cholesterol induced atherosclerosis in rabbits by feeding an organic iodine compound. Rivers presents a biological test for the diagnosis of psittacosis. The studies of Rhoads on various types of hematopoietic disturbances are continued.

Apparatus and Technique for Roentgenography of the Chest 1935 Charles Weyl and S. Reid Warren, Jr. 166 pp Springfield and Baltimore Charles C. Thomas \$5.00

This volume of 166 pages is divided into four chapters and an appendix.

Chapter one is a summary of the phenomena associated with the production of chest roentgenograms. Chapter two is devoted to a discussion of radiographic apparatus including not only that necessary for the actual taking of films but also the various devices used for the dark-room technique. The technical procedures for the taking of films of the chest and their development are covered in detail in chapter three. In chapter four the physical measurements for determining, and apparatus used, for the output of x-ray machines and the quality of x-ray films are described. In the appendix the elementary electrical theories are discussed.

The material is so arranged that reference is easy. There are several diagrams and valuable tables. The book is designed for the roentgenologist rather than the technician.

The authors believe, and your reviewer agrees with them, that a thorough understanding of the physical principles underlying the making and processing of x-ray films of the chest is a necessary part of roentgenological training. For the lay tech-

nician the book is perhaps a little too theoretical and the data for guidance in individual exposure lacking.

Six Conférences de Physiologie Leon Binet 73 pp Paris Masson et Cie 12 fr

This booklet assembles the contributions made to physiology during the last few years in the laboratory of physiology of Professor Binet. It includes experiments on the lungs, the suprarenal capsules, nerve tissue, induced hyperthermy and on the use of fish both in physiology and in toxicologic assay. These conferences should be of interest and value to the student of physiology.

Oxford Medical Publications Gastritis and its Consequences Knud, Faber 119 pp London Oxford University Press \$3.00

This excellent monograph is comprised of the three Guy's Hospital Medical School lectures delivered by the author in November, 1934. The subject material covers the extensive field from the early pathological studies of the author through the very recent concepts of the relation of gastritis to polyposis, pernicious anemia, and gastric cancer.

Faber frankly acknowledges the "stamp of his own personal views", but he has supported his opinions not only with well-chosen pathological data and logical analysis, but also with contributory data from other workers. The conclusions are neither dogmatic nor biased, and the whole tenor of the book is stimulating and thought provoking. It is well worth reading with great care, even though one cannot accept it entirely without reservations.

Docteur Carlos J. Finlay Son centenaire 1833-1933 Decouverte 1881 Francisco Dominguez 302 pp Paris Librairie Louis Arnette.

The name of Doctor Carlos Finlay is unfortunately only too little known in the United States. Although his medical education and early training were obtained in this country, his many important medical contributions were accomplished in Cuba, where he was considered a genius. Finlay's studies of yellow fever were epoch making and practically laid the entire basis for Cuba's present-day sanitation system. In fact his biographer considers his discoveries as the greatest made in America in the nineteenth century.

Confined primarily to extensive and minute studies of the various phases of yellow fever, his versatility extended, however, to other medical fields. Exophthalmic goitre, cholera, tetanus, electrotherapy, leprosy, filariasis, trichiniasis, beriberi, tuberculosis and even ophthalmology (to which he contributed a new operation for cataract) received his studied attention. The present volume which is published through the efforts of the Cuban government under the auspices of the Finlay Centenary Committee, reviews his more important work and recounts the highlights of his career.

The outing was successful in a "get together" as the foursomes were arranged to include both medical and dental men.

DR. BURWELL'S POSITION ON THE STAFF OF THE PETER BENT BRIGHAM HOSPITAL

Dr Charles S Burwell, Dean of the Harvard University Medical School, has been appointed to the position of Physician on the Staff of the Peter Bent Brigham Hospital

RECENT DEATHS

GOODELL—GEORGE ZINA GOODELL, M D, of 5 Williams Street, Salem, Massachusetts, died at his home September 9 after a long illness. He retired from practice several years ago. Dr Goodell was born in Salem in 1859 and after graduation from the high school studied at and graduated from the Harvard University Medical School in 1881.

He joined the Massachusetts Medical Society in 1881 and retired in 1933. He devoted his major activities to diseases of the ear, nose and throat. He served on the staff of the Salem Hospital from 1883 to 1894 and in 1889 and 1890 was Superintendent of that institution.

He was treasurer of the Essex South District Medical Society for twenty five years and was a member of the New England Society for Physical Therapeutics, Essex Lodge of Odd Fellows and the local lodge of United Workmen.

Dr Goodell is survived by his daughter, Mrs Raymond H. Odeil, two brothers, Frank T. and Oliver W. Goodell, and two sisters, Mrs George E. Patterson and Mrs Walter P. Pratt, all of Salem.

HALE—EDWARD P. HALE, M D, of Lenox, Massachusetts, aged seventy five, died at his home September 9, 1935. Dr Hale was born in Danvers, Massachusetts, and graduated from the Bellevue Hospital Medical College in 1881. He practiced in Vermont and also was resident physician at the Danvers State Hospital for a brief period before settling in Lenox.

He was president of the Lenox Savings Bank, a trustee of the Lenox Academy and a member of the Massachusetts Medical and local Societies.

Dr Hale is survived by his widow, Mrs Anna P. (Walker) Hale.

CRONIN—THOMAS JOSEPH CRONIN, M D, of 29 Forest Street, with an office at 36 Pleasant Street, Worcester, Massachusetts, died at the Memorial Hospital, Worcester, September 10, 1935.

Dr Cronin was born in 1865 at Braidwood, Illinois, the son of Mr and Mrs Henry D. Cronin. Early in his life the family moved to Millbury, Massachusetts, where his preliminary education was acquired, later he attended the College of Pharmacy in Boston. He graduated in medicine from the Baltimore University School of Medicine in 1898. Before settling in Worcester, he practiced for several years in Webster, Massachusetts. For many years he was eye, ear, nose and throat consultant

at the Fairbairn Hospital. He joined the Massachusetts Medical Society in 1898 and was also a Fellow of the American Medical Association.

Dr Cronin was prominent in Masonic circles, the Worcester Economic Club and the Central Congregational Church, Worcester. He is survived by his widow, Mrs Louise (Schwegler) Cronin, two daughters, Miss Dorothy Cronin and Mrs Frank L. Harrington, a brother, John D. Cronin, and a sister, Mrs Nellie Feehan, both of Millbury.

NOTICES

IMPORTANT ANNOUNCEMENT TO PHYSICIANS AND HOSPITALS

Due to physicians' unfamiliarity with Government requirements in submitting charges, more than 50,000 accounts submitted by physicians and hospitals in Civil Works Administration injury cases were returned for correction, or held for further information, necessitating undue delay in payment, because of one or more discrepancies.

As a former supervising auditor of the U. S. Employees' Compensation Commission, I have condensed to a four page booklet under the title "Instructions to Physicians and Hospitals for Submitting Charges in Federal Injury Cases," the numerous requirements scattered throughout 60 detailed pages of the Government's regulations, each point being separately paragraphed and headed for the most convenient reference.

The following points are covered:

- Authority for treatment
- Medical and x-ray reports
- X-ray films
- Charges in disease cases
- Postmortem examinations
- Dental charges
- Charges for drugs
- Charges for appliances
- Physicians owning hospitals
- Payment for personal property
- Submission of x-ray charges
- Charges for blood
- Itemization of accounts
- When to submit charges
- Joint accounts
- Required signatures
- Hospital charges
- Nurses' charges
- Assistants and consultants' services

In addition to the foregoing the booklet covers several important points such as inquiry as to payment of accounts, time required for receipt of remittances after payment is authorized, how charges may be expedited for payment, and other valuable information to physicians and hospitals having charge in Federal injury cases.

This booklet is neatly prepared, has a durable cover, and is convenient for pocket or office use.

It is an accurate and ready reference, covering every requirement, a guide to cooperation and the avenue to correct submission and the earliest possible payment of accounts. This guide will save time money worry and waiting.

With an increasing number of people being employed subject to Government compensation benefits, and with the near possibility of an added number of physicians being called upon to serve their Government as a result of recent social legislation every physician should familiarize himself with Government requirements in respect to charges.

Price \$1.00 the copy postpaid. The price is negligible in comparison with the booklet's practical and beneficial value. Order now.

C. B. RIDDLE.

Washington D. C., P. O. Box 442

DR. WILLIAM P. MURPHY ASSUMES INDEPENDENT PRACTICE

Dr. William P. Murphy formerly associated with Dr. Edwin A. Locke and Dr. George R. Minot, will continue his office and consultation practice independently at his present address 311 Beacon Street, Boston Massachusetts.

DR. S. F. MARSHALL JOINS THE LAHEY CLINIC

Dr. Frank H. Lahey wishes to announce that Dr. Samuel Frederick Marshall who for the past ten years has been associated in surgery with the Henry Ford Hospital in Detroit, Michigan has been appointed as one of the surgeons to the Lahey Clinic.

WORCESTER NORTH CANCER CLINIC Burbank Hospital Fitchburg Massachusetts

NOTICE TO MEMBERS OF THE WORCESTER NORTH DISTRICT MEDICAL SOCIETY

September 11 1935

My dear Doctor

There will be a consultation cancer clinic September 24 at the Burbank Hospital 9:30 a.m. to 12:30 p.m. The consultants are Dr. Grantley W. Taylor visiting surgeon to the Massachusetts General Huntington Memorial and Pondville Hospitals and Dr. Charles C. Lund visiting surgeon to the Boston City and Huntington Hospitals.

We hope you will use this opportunity to be present with or refer by note any of your patients having cancer or suspicious of a malignant condition.

In order to facilitate the clinical routine we would appreciate the patients arrival at 9 o'clock. It has proved in other consultation clinics of value to have available any history regarding the patients condition. For your convenience in this matter we would be very glad to have you telephone at any time Fitchburg 4807 to give information to the clinic clerk Miss Irma Holmes.

We will appreciate your active participation with the clinic.

Very truly yours

WORCESTER NORTH CANCER COMMITTEE

DR. F. H. THOMPSON SR., *Chm.*

ANNOUNCEMENT

CLARK W. HEATH M.D., has opened an office at 319 Longwood Avenue Boston Mass.

REPORT AND NOTICE OF MEETINGS

THE FOUR COUNTY MEDICAL SOCIETY

An interesting day was spent by the men who attended the meeting of the Four County Medical Society in Greenfield on Wednesday September 11. A series of case presentations was made by Greenfield doctors at the Franklin County Hospital and the following papers were presented:

Hyperthyroidism Dr. F. B. Sweet of Springfield
Some Problems in Gall Bladder Surgery Dr. I. S. F. Dodd of Pittsfield
Some Observations on the Use of Eripal and Avertin by Dr. E. A. Knowlton of Holyoke
Femoral Hernia—The Inguinal Approach by Dr. F. Hegler of Springfield
The State Pneumonia Program by Dr. R. Heffron of Boston

The President of the Massachusetts Medical Society Dr. Charles Mongan, addressed the gathering in his usual pleasing manner. He stressed the importance of public-minded physicians and outlined the transactions taking place in Washington relative to the Social Security Law. Doctor Mongan placed especial emphasis on the need of cooperation and felt that we could best use our abilities in educating and molding public opinion on matters of socialized medicine.

An excellent luncheon was served at the Hotel Weldon and many of the doctors attending took advantage of the invitation of the Greenfield Golf Club to play on its links during the afternoon.

J. A. WHITNEY *Secretary*

THE CARNEY HOSPITAL CLINICAL MEETING

September 23 1935 3 P.M.

The Clinical Diagnosis of Jaundice Dr. Howard M. Clute. Lantern Slides
The Technique of Arthroplasties Dr. W. R. McAneland. Motion Pictures
Physicians and medical students invited.

nervous diseases. However in the latter chapter the author seeks to correlate these two subdivisions and by the use of photomicrographs and a few colored plates makes out an excellent and interesting case for the relationship between sinusitis and mental disease. The final chapter is devoted to a résumé of illustrative case histories, and there is an appendix describing the technique for preparation of gross and microscopic specimens. A long list of bibliographic references is appended.

The text is at times annoyingly replete with references to other authors, a feature which tends to break up both the author's and the reader's train of thought.

Studies from The Rockefeller Institute for Medical Research Reprints Volume 93 593 pp New York The Rockefeller Institute for Medical Research

In this volume the experimental studies of Webster and his associates on the St. Louis encephalitis virus are continued. There is the usual wide range of material from the fields of organic chemistry, chemical pharmacology, physical chemistry, and general physiology. From the department of the hospital there are several papers of interest. Page and others present further work in the field of hypertension, and Page also has a report on the prevention of cholesterol-induced atherosclerosis in rabbits by feeding an organic iodine compound. Rivers presents a biological test for the diagnosis of psittacosis. The studies of Rhoads on various types of hematopoietic disturbances are continued.

Apparatus and Technique for Roentgenography of the Chest 1935 Charles Weyl and S. Reid Warren, Jr. 166 pp Springfield and Baltimore Charles C. Thomas \$5.00

This volume of 166 pages is divided into four chapters and an appendix.

Chapter one is a summary of the phenomena associated with the production of chest roentgenograms. Chapter two is devoted to a discussion of radiographic apparatus including not only that necessary for the actual taking of films but also the various devices used for the dark-room technique. The technical procedures for the taking of films of the chest and their development are covered in detail in chapter three. In chapter four the physical measurements for determining, and apparatus used, for the output of x-ray machines and the quality of x-ray films are described. In the appendix the elementary electrical theories are discussed.

The material is so arranged that reference is easy. There are several diagrams and valuable tables. The book is designed for the roentgenologist rather than the technician.

The authors believe, and your reviewer agrees with them, that a thorough understanding of the physical principles underlying the making and processing of x-ray films of the chest is a necessary part of roentgenological training. For the lay tech-

nician the book is perhaps a little too theoretical and the data for guidance in individual exposures lacking.

Six Conférences de Physiologie Leon Binet 73 pp Paris Masson et Cie 12 fr

This booklet assembles the contributions made in physiology during the last few years in the laboratory of physiology of Professor Binet. It includes experiments on the lungs, the suprarenal capsules, nerve tissue, induced hyperthermy and on the use of fish both in physiology and in toxicologic assay. These conferences should be of interest and value to the student of physiology.

Oxford Medical Publications Gastritis and Its Consequences Knud Faber 119 pp London Oxford University Press \$3.00

This excellent monograph is comprised of the three Guy's Hospital Medical School lectures delivered by the author in November, 1934. The subject material covers the extensive field from the early pathological studies of the author through the very recent concepts of the relation of gastritis to polyposis, pernicious anemia, and gastric cancer.

Faber frankly acknowledges the "stamp of his own personal views", but he has supported his opinions not only with well-chosen pathological data and logical analysis, but also with contributory data from other workers. The conclusions are neither dogmatic nor biased, and the whole tenor of the book is stimulating and thought-provoking. It is well worth reading with great care, even though one cannot accept it entirely without reservations.

Docteur Carlos J. Finlay Son centenaire 1933 Sa Découverte 1881 Francisco Dominguez 302 pp Paris Librairie Louis Arnette

The name of Doctor Carlos Finlay is unfortunately only too little known in the United States. Although his medical education and early training were obtained in this country, his many important medical contributions were accomplished in Cuba, where he was considered a genius. Finlay's studies of yellow fever were epoch-making and practically laid the entire basis for Cuba's present-day sanitation system. In fact his biographer considers his discoveries as the greatest made in America in the nineteenth century.

Confined primarily to extensive and minute studies of the various phases of yellow fever, his versatility extended, however, to other medical fields. Exophthalmic goitre, cholera, tetanus, electrotherapy, leprosy, filariasis, trichiniasis, beriberi, tuberculosis and even ophthalmology (to which he contributed a new operation for cataract) received his studied attention. The present volume which is published through the efforts of the Cuban government under the auspices of the Finlay Centenary Committee, reviews his more important work and recounts the highlights of his career.

NUMBER 13

EXPECTED LAGS BETWEEN CLINICAL DIAGNOSIS AND X RAY CONFIRMATION*

BY HENRY A. CHRISTIAN, M.D.†

IN the great progress that has been made in the application of roentgenology to diagnosis, and none would fail to acknowledge this progress to have been a tremendous one clinicians often lose sight of certain inevitable limitations to this valuable method of diagnosis. Limitations invariable by reason of the relationship between the x ray and its penetration through different tissues in the body and through different substances that can be introduced into the body. As a result of this they may accept a negative x ray report as contra-indicating a diagnosis made on clinical grounds. With proper understanding of the matter this should not occur.

Until certain structural changes which are demonstrable by x ray, have occurred, there is nothing that can be demonstrated by x ray. In some diseases such structural changes never occur; in others they occur only after well marked symptoms have developed; in still others structural changes demonstrable by x ray and symptoms appear almost simultaneously, not infrequently the changes demonstrable by x ray antedate the development of definite symptoms. In the first group come diseases like typhoid fever, Bright's disease, cirrhosis of the liver, many diseases of the central nervous system etc. in which x ray gives no help in diagnosis. It is the second group to which at this time I will direct attention for reasons already indicated in earlier sentences of this paper, giving some examples of what I term expected lag between clinical and x ray confirmation.

Severe, persisting backache is a common condition. As probable causes we recognize, among others, osteoarthritis of the spine and neoplasm of the vertebrae. The aid of roentgenology is sought. Clinically there is strong suspicion that neoplasm is the causative factor. The roentgenologist reports no evidence of neoplasm involving the bone, or he may report evidences of osteoarthritis. Does such report justify the clinician in giving up his diagnosis of neoplasm? No. I have observed patients with such x ray reports in whom the pathologist soon could dem-

onstrate neoplasm or in whom later on the x ray showed tumor, if arthritis was present, it was not a cause of pain. I will cite briefly such a patient.

A woman of fifty-two came to the hospital complaining of pain in the back of four months duration, recently very severe. The right lobe of the thyroid was enlarged, irregular and very hard. The diagnosis of malignant tumor of thyroid with metas-

FIGURE 1 1st, 2nd and 3rd lumbar vertebrae showing tumor metastases.

tases in the spine was made and this patient was demonstrated by me as such at a clinic held on November 22. The x ray report on November 8 was as follows: "Anteroposterior films of thoracic and lumbar spine and pelvis show no evidence of metastases. There are only slight arthritic changes." X ray repeated on November 20 was reported as follows: "Anteroposterior stereo of the spine and lateral shows no definite evidence of metastasis. Vertebrae appear slightly decalcified, and there are changes in the articular processes of fourth and fifth thoracic but these probably are

*Read by title at meeting of Association of American Physicians, Atlantic City, May 7 and 8, 1935.

†Christian, Henry A.—Harvey Professor of the Theory and Practice of Physic, Harvard University Medical School. For record and address of author see "This Week" issue, page 52.

arthritic" The patient died December 17, and at autopsy there was found carcinoma of the thyroid with metastases to regional tissues, mediastinum, liver, lungs, vertebrae, ribs, left iliac bone and in tercostal muscles. What particularly interests us in this connection are the findings in the vertebrae not revealed by x-ray but obviously of a nature to be the cause of the pain in the back that the patient complained of. "On examining the vertebral column the second lumbar vertebra is seen to be involved by tumor growth. It is extremely soft and presents a reddish gray color instead of white. It is so soft that slightest pressure causes a compression of the vertebra. A saw cut made through the first, second and third lumbar vertebrae (fig 1) shows that the entire anterior half of the second lumbar vertebra is completely destroyed by tumor tissue. The bone is extremely soft, reddish gray in color, almost fluid in consistency. The posterior half also is involved by tumor. Here the tissue is firmer and has a more whitish gray aspect. The first lumbar vertebra also shows a large tumor nodule approximately $1\frac{1}{2}$ cm. in diameter, which is reddish gray in color and shows a central area of necrosis of approximately 1 cm in diameter. Here the tissue is fluid in consistency. The third lumbar vertebra shows a similar area of metastasis, which is approximately $1\frac{1}{2}$ cm in diameter, the larger portion of which is necrotic and fluid in consistency."

It is well to remember in this connection that after the age of fifty, osteoarthritic changes in the spine are very frequent, they may be symptomless, even when very marked as shown by x-ray.

Pleural fluid, recurring several times following paracentesis, in a patient without evidences of cardiac insufficiency justifies a clinical diagnosis of neoplasm as the cause even when the roentgenologist reports no evidence of tumor. The interval between such clinical diagnosis and x-ray confirmation may be a long one as shown by the following history:

A man, aged 49, was admitted to the hospital on October 24, 1932 with the physical signs of right-sided pleural effusion. He had previously been in the Out Door Department and on October 6, 1932 an x-ray showed the right diaphragm obscured by fluid which rose in the axilla, the right chest appeared flattened and the right lower border of the lung was atelectatic, fluoroscopy showed a collection of fluid in the septum between the upper and lower lobes on the right, the posterior mediastinum was clear.

On the day of admission to the hospital 1,400 cc of fluid was removed from the right chest with a specific gravity of 1.018 and a cell count of 24 lymphocytes and 41 red blood cells. No bacteria could be found either microscopically or on culture. On November 3, 1,100 cc fluid was removed from the same chest on November 15, 1,050 cc. and on November 25, 700 cc.

He remained in the hospital until November 29, 1932. On November 26 the sixth x-ray examination of his chest gave the following: "Stereo x-ray still shows mottling of the right lower lobe but only a small amount of fluid. The process in the right upper posteriorly is unchanged. There is no essential change since previous examination." The previous examination contained the statement "there is no evidence of neoplasm."

During his stay in the hospital this patient was

demonstrated by me in a clinic as an example of pleural effusion due to neoplasm though x-ray had failed to show any evidences of this.

He was readmitted to the hospital on February 28, 1933 and remained until March 4, 1933. During this stay his chest was tapped twice, once with the removal of 1,600 cc and once with the removal of 400 cc. Careful study of various fluids showed no cells suspicious of tumor origin.

On March 3, 1933, a ninth roentgen examination of the chest was reported to show only slight further clearing of the right base. There was still enough fluid to obliterate the diaphragm and costophrenic angle. Fluoroscopy gave no additional information. Five months after the first x-ray showing fluid in the pleura there was still no x-ray evidence of tumor.

This patient was lost sight of until, on March 15, 1934, in a letter from Dr. E. D. Churchill of the Massachusetts General Hospital in regard to him the following statement is made: "Several weeks ago I explored this man's chest and found a primary carcinoma of the lung situated in the upper lobe with metastasis to the visceral pleura in the upper mediastinum. Microscopic section of a biopsy from this metastasis showed adenocarcinoma." This operation was almost a year and a half after pleural fluid had developed and nearly as long since the patient had been presented in a clinic as an example of pleural fluid due to tumor.

Prolonged fever often is difficult to explain. In the absence of demonstrable causes of various sorts, neoplasm should be considered as the cause and diligently sought for by all possible methods of examination including of course x-ray studies such as may be applied. Sometimes such x-ray studies are negative, when later they demonstrate a neoplasm, in other words, a neoplasm causing the symptoms of prolonged fever may fail to show in x-ray until further time has elapsed for the neoplasm to progress to x-ray visibility. Bone metastases may become demonstrable later and explain such a fever, just as has been indicated in the instance of back pain. Lung tumor similarly may become demonstrable as in the following patient.

A woman of sixty-four came to the hospital on February 3 with the story that for some four months there had been progressing fatigue, some cough, fever, a marked change in personality with depression and with recent confusion and disorientation. On December 22 she had been seen by a colleague, who could not make an adequate diagnosis, physical examination gave no definite findings. A week before he saw her, an x-ray examination of her chest, made on account of cough, had shown only slight peribronchial enlargement at the right hilus. When she came to the Peter Bent Brigham Hospital on February 3 the liver was considerably enlarged, and there were signs of fluid, small in amount, in each pleural sac. X-ray of the chest showed a small, rounded mass in the right hilus, 3.5 cm in diameter, suggesting to the roentgenologist a metastasis rather than primary carcinoma. There was a small amount of fluid in each costophrenic angle, slightly more on the left. She died on February 14, and autopsy showed primary bronchiogenic carcinoma at hilum of right lung with extensive metastases. Neoplasm was the cause of the fever and other symptoms.

A patient's history may be strikingly indicative of pulmonary abscess following tonsillectomy.

tomy, extraction of teeth or pneumonia. There is fever, sputum may be abundant, sometimes foul, physical signs indicate a local pulmonary process, a clinical diagnosis of lung abscess is made, x ray shows no evidences of abscess but does show a localized shadow from infiltration of the lung, a pneumonic consolidation, later a repeat x ray shows a suggestion of abscess the next x ray shows an abscess cavity, probably with fluid level. The x ray lag in such cases may be very long as in the following patient (42970) but it averages in my experience about ten days.

A Negro man aged forty was admitted to the hospital May 28 1933 giving the following history. For approximately one month the patient has had a paroxysmal cough productive of large amounts of foul-smelling sputum. During this period he has had drenching night sweats. On the morning of admission during a paroxysm of coughing he had a sensation of something giving away in his left upper chest, and immediately thereafter he raised a large quantity of extremely foul-smelling sputum. There is no history of aspiration of foreign body or previous cold in the chest. Two years ago the patient had a tooth extracted and he has had dental caries for years.

Physical examination of the lungs showed a normal right lung. On the left side behind from the mid portion of the scapula half way down to the base there was moderate dullness in an ill-defined area. Over this area breath and voice sounds were slightly diminished, but breath sounds were harsh in character and at times suggestively tubular. There were numerous coarse râles on both inspiration and expiration. The rest of the left lung seemed normal. The clinical diagnosis of lung abscess was made.

On May 9 stereo x ray of the chest showed the right lung to be clear. There was diffuse clouding through the middle third of the left lung with a slight increase in the markings extending toward the base. "The process is apparently in the posterior portion of the chest and is probably in the upper portion of the lower lobe. No definite cavity formation seen. Impression pneumonic process in the left lower lobe."

Two weeks later on May 23 re-examination of the chest showed a definite spread of the process in the left lung which now involves the upper two-thirds most marked around the hilus. "There are now several indistinct small clear areas posteriorly which may be beginning cavities. Heart and trachea are not displaced. Impression pneumonic consolidation, probably beginning pulmonary abscess."

A third x-ray examination on June 10 a month after the first one, showed the extent of involvement slightly less than at previous examination with clearing of the lower portion. "There is now a definite cavity rather deep in the lung in line with the first interspace anteriorly fifth rib posteriorly 6 cm. from the midline. There is definite clouding of the pleura over the left upper lobe. Left diaphragm is elevated and slightly limited. Impression pulmonary abscess."

Additional x rays were taken and on July 14 the fifth x-ray examination of the chest showed marked clearing of the process in the left upper lobe, and the cavity had disappeared. "There is now only slight consolidation around the left hilus extending into the left upper lobe. Right lung remains clear."

It might be put thus, something in the lung that is not, namely a cavity is not roentgenological

ally demonstrable, if the surrounding exudation in the pulmonary tissue in relation to the cavity is relatively extensive, or if the cavity is filled with exudate similar to that in the surrounding parenchyma. These are conditions which exist almost always in some stage of lung abscess and hence the delay in their demonstration by x ray.

Bronchial stenosis often gives definitive physical signs when x ray may show no positive evidences of change in the lung parenchyma. X ray obviously, may fail to show anything to indicate the obstructing lesion in the bronchus, if there is no peribronchial lesion at the point of the partial stenosis. Later on, when obstruction becomes more marked, x ray will demonstrate the partial or complete airlessness of that portion of the lung.

Osteomyelitis is another condition in which there should be recognized a very considerable lag between symptoms and x ray confirmation of diagnosis, whether we are dealing with long bones or flat bones. In mastoiditis, not realizing this may cause serious delay in performing the needed operation. Cause of symptoms indicating septicemia may be missed by reason of x ray not showing osteomyelitis, let us say in the femur. The lag in osteomyelitis is variously stated as one to several weeks.

Arthritis is still another example. It is surprising often how little the x ray can demonstrate in a very obvious disabling rheumatoid arthritis after a long duration of symptoms. Gouty changes in joints notably may give no evidence of gout when the joints are studied roentgenographically. The roentgenologist is not justified in saying, as he sometimes does, by x ray this condition is chronic osteoarthritis not gout. Often one sees deposits of uric material on the cartilaginous surfaces of joints which in no way could be evident in the x ray film.

I have proved a pulmonary tuberculosis, suspected from history including recent hemoptysis and from the hearing of a few localized râles, by finding tubercle bacilli at a time when the x ray showed no lesion, later x ray revealed a parenchymal lesion in the region where râles had been heard. Of course far more frequent is it for the x ray to reveal pulmonary tuberculosis, only suspected from history, of whose occurrence no other evidence could be found.

Also there may be a lag between symptoms and x ray demonstration of cancer of the stomach or bowel. Sometimes the clinical story is so suggestive as to point definitely to the diagnosis and yet x ray is not confirmatory, much more often the clinical picture is only definite enough to suggest some disturbance of stomach or bowel. I have seen some definite examples of failure of the x ray to show the lesion in stomach or bowel in such patients when repeat x rays a few weeks later showed unmistakable

evidence of cancer, this has occurred oftenest with cancer of the stomach, less frequently with cancer of the intestine

Very probably other examples might be offered, but I am not attempting a full category of conditions in which a lag between clinical diagnosis and x-ray confirmation can occur. I am merely pointing out that it not infrequently does occur.

In the above I have sought to present by a few examples a phase of the problem of x-ray in diagnosis, all too often not sufficiently realized by clinicians and not appreciated by poorly trained roentgenologists. For him who understands the fundamental principles of x-ray in diagnosis, and this of course includes all well-trained roentgenologists, it is not necessary to point out that in some conditions a lag between clinical diagnosis and x-ray confirmation is to be expected, a lag which lengthens with the increased experience and diagnostic acumen of

the clinician, and which shortens with the increased experience and skill of the roentgenologist and with improvement in the apparatus with which he works. As clinicians, we should not demand the impossible of roentgenology. The possible, however, is of the very greatest help in diagnosis, and this clinicians should acknowledge.

From the above discussion the superficial reader might draw the conclusion that the author is belittling the value of the x-ray in diagnosis. This is not the case, both positive and negative x-ray findings are of the very greatest value in diagnosis in confirming or ruling out suspected lesions as well as in not infrequently revealing lesions totally unsuspected from history and physical examination. However, it needs to be recognized that there are definite limitations to what x-ray methods can show, and these limitations should be better recognized by both clinicians and roentgenologists.

ELECTROSURGICAL CHOLECYSTECTOMY*

I Experimental Observations

BY LESTER R. WHITAKER, M.D.†

HEMORRHAGE is the primary consideration and the chief danger in section of the tissues. Before the days of anesthesia attention was paid only to gross bleeding which was controlled by the tourniquet or mass ligation. The surgeon had no time to spend clamping and tying small vessels. He worked with utmost speed in the effort to finish his operation before the patient died of pain, hemorrhage, and shock. The old tradition of haste still exerts a surprising influence on surgical technique. Even though anesthesia gave the operator a quiet patient and time in which to do careful anatomical dissection, individual ligation of vessels, and other refinements, many to this day rush through even a simple operation as if they expected the patient to die before they could finish. Among surgeons of past generations there was a dictum that no major abdominal operation should consume more than one hour of time, if it approached two hours, there was danger of losing the patient. These surgeons acted accordingly. They made large incisions, handled the tissues hurriedly and roughly, exposed viscera to chilling and drying, and ligated only the vessels which spurted in their faces. After an hour of this of course the patient was almost invariably in a condition of shock.

Gradually a school was developed, of which

*From the Evans Memorial for Clinical Research and Preventive Medicine, the Surgical Clinic of the Massachusetts Memorial Hospitals, and the Boston University School of Medicine.

†Aided by a grant from the Committee for Scientific Research of the American Medical Association.

The author is indebted to Drs. Adrian Solo and Thomas A. Kelley for assistance in this work.

†Whitaker, Lester R.—First Assistant Visiting Surgeon, Massachusetts Memorial Hospitals, Boston. For record and address of author see "This Week's Issue" page 632.

Halsted was a leader, where men began thinking for themselves with regard to the adaptation of treatment to conditions, rather than learning technique in an apprenticeship manner. These men took advantage of the extra time allowed by anesthesia to handle and pack away viscera carefully, make anatomical dissections, ligate individual bleeders, and in closure of the wound to obtain apposition of tissues. These methods had the advantages of producing the least trauma and disturbance of the anatomy, and allowing less opportunity for collection of blood and serum in the wound, thus favoring primary healing and rapid recovery of the patient. Any surgical operation is an insult to the human frame, it should be made as light as possible.

The great advantage of electrosurgery is in control of hemorrhage. The cutting current (acusection) seals the capillaries and small vessels, preventing oozing, and allowing the "spurters" to be more easily and accurately clamped. Medium-sized vessels can be snapped and the tissue in the jaws of the clamp coagulated by holding in contact with the active electrode. Larger vessels, however, should not be treated in this way because the coagulum loosens after a day or two and there is risk of secondary hemorrhage. Tissue to be removed, such as tumors, may be handled either by direct attack with the cutting current, using a loop electrode, or after electrocoagulation en masse. The former can be used only in case the tissue is not too vascular. *In very vascular tumors, or organs such as the liver, kidney, and spleen, masses of tissue must be treated first with the coagulating cur-*

rent by insertion of a needle electrode at intervals, reducing the tissue to a firm coagulum which can then be removed by the cutting current without hemorrhage.

Pribram in 1928, published a method of treating the acutely inflamed, gangrenous, or sclerotic gall bladder with the cautery to dispose of it and at the same time reduce the danger of hemorrhage. By sterilizing the infected mucous membrane and tissues of the gall bladder with the actual cautery Pribram felt that he had avoided the necessity for drainage. The description of Pribram's method follows:

"In order to avoid injury to the liver tissue in cases where subserous resection (shelling out) was not successful, I have tried another way in order to be able to close the abdominal cavity. The vesicle is completely emptied of its liquid contents by the water pump then split through the middle with the scissors from the fundus to the cystic duct, and the stones removed. The exposed cystic duct is cut between two ligatures. Then the mucous membrane is completely charred with a cautery down to the serosa. In this way any abscess of the wall penetrating the liver is completely destroyed. Then the two edges of the gall bladder are sewn exactly together. To this procedure I have given the name 'mukohase' (destruction of mucosa). It has proved entirely satisfactory in all the cases where I have used it and is the method of choice for making a complete wound closure in complicated cases."

Pribram recommends the procedure in cases of shrunken gall bladder where resection is difficult because of sclerosis, also in badly infected and gangrenous stone-containing vesicles, and in empyema. He has had only three deaths in two hundred cases, a remarkable record. He attributes the rapid convalescence and low mortality partially to the absence of drainage, avoiding, as he believes, peritonitis, acute dilatation of the stomach, erosion of blood vessels with secondary hemorrhage, postoperative pulmonary and cardiac complications.

The first impression from reading a description of Pribram's method was that the use of an actual cautery deep in the abdominal cavity was rather heroic, especially in close proximity to such vital structures as the bile duct and associated vessels. The second thought was that a great deal of dead tissue was left to be absorbed. And thirdly, it seemed rather doubtful that this could be done safely without drainage. However, in favor of the method were Pribram's remarkable results, statistics which compared favorably even with those where only a slightly diseased gall bladder had been removed by the usual dissection method.

EXPERIMENTS WITH OBLITERATION OF THE GALL-BLADDER BY DIFFERENT MEANS

Where possible of adaptation every radically new technical procedure in abdominal surgery should be tried first upon the dog. The originator of a method may be very skillful in its use but an imitator naturally cannot be until he has had considerable practice. Let this risk be taken by the dog. For several years I have been concerned with methods for removing or obliterating the gall bladder with the greatest safety and the least possible disturbance to the patient. William J. Mayo, in 1900, presented a method for removal of the mucous membrane of the gall bladder as a substitute for cholecystectomy. He considered that if the mucous membrane were removed the gall bladder would become obliterated. I tried the removal of the mucous membrane in gall bladders of dogs but found it extremely difficult to make the dissection, and came to the conclusion that cholecystectomy would be more easily performed, particularly the subserous removal described by Doyen. By using a headlight and special retractors a gall bladder not too sclerotic can be removed subserously through a very small incision, allowing the patient to make an extremely rapid recovery. With one patient having gall stones who was a poor risk for cholecystectomy a method of destroying the mucous membrane of the gall bladder was tried by chemical cauterization. Although several attempts were made to obliterate the sinus with formalin, carbolic acid, and alcohol, the mucous membrane would regenerate each time and the opening remained until the patient died of cancer of the rectum about a year later. The difficulty with all operations upon the mucous membrane is the achievement of total destruction. Experiments upon dogs have shown that even a small section left near the cystic duct will regenerate.

AN ATTEMPT TO OBLITERATE THE GALL-BLADDER BY CAUTERIZATION OF THE CYSTIC DUCT

The publication of Pribram's method renewed my interest in these safer and less traumatic methods for removal of the gall bladder. It seemed possible to go a step farther than Pribram. By his method considerable tissue of the gall bladder had to be sloughed and absorbed, yet good results were obtained. The lymphatics and veins of the gall bladder are in the wall of the cystic duct. Why could not one by destroying this vital part of the gall bladder produce necrosis of the vesicle, allowing it to slough away through a drainage tract, thus accomplishing its removal in patients who were poor risks by an easy technical procedure with little trauma? A piece of iron was fashioned to fit the outlet of the cystic duct in a dog. Then with a small abdominal incision and the gall

bladder opened at the fundus the iron was heated, not red hot, but enough to produce some searing of the tissue. When applied inside the cystic duct it had a tendency to stick to the mucous membrane, requiring considerable force to tear it away. After cauterization a soft rubber tube was placed in the gall-bladder, taking care not to press it down into the duct enough to produce necrosis of the wall. This method was tried in three dogs. One of them, sacrificed after one day, showed the gall-bladder collapsed around the drainage tube, edematous and inflamed, with a slight injection of the surrounding peritoneum. Another dog, sacrificed after eight days, had peritonitis, the gall-bladder was necrotic, and cystic duct leaking. The third dog made only a fair postoperative recovery for three days but was lost, no autopsy being performed. These poor results led us to discard the method of destruction of the gall-bladder by cauterization of the cystic duct.

AN ATTEMPT TO OBLITERATE THE GALL-BLADDER BY CAUTERIZATION OF THE MUCOSA

With ten dogs the whole mucosa of the gall-bladder was cauterized to varying degrees, a soft drainage tube being placed inside. In four, light cauterization was done. These made good immediate postoperative recoveries. One dog, sacrificed after one day, showed a gall-bladder collapsed about the tube and inflamed with adhesions to the omentum. Two, sacrificed after six and eight days, showed no peritonitis, but adhesions of omentum to a sloughing gall-bladder, with one of them, however, the slough was small, and it was considered that the gall-bladder would have been obliterated. Another dog, sacrificed after eleven days, showed peritonitis with omental adhesions around a necrotic gall-bladder.

Out of the six dogs in which moderate cauterization was done, three had peritonitis, one with a hole from the gall-bladder into the peritoneal cavity. The three other dogs, sacrificed after one to twelve days, had necrotic gall-bladders covered by omental adhesions, one with damage to the liver.

In two additional dogs the gall-bladder was damaged by clamping eleven days previous to the cauterization, the gall-bladder was rendered slightly thickened and sclerotic thereby. In these two the whole mucosa of the gall-bladder was cauterized by the hot iron and a soft drainage tube was placed inside. Both dogs made good immediate postoperative recoveries, one showed slight damage to the liver about the gall-bladder, with adhesions, the other, no adhesions, neither had peritonitis, and the ducts were normal. Apparently the actual cautery worked better in the slightly sclerotic gall-bladder.

In two cats the mucosa of the gall-bladder was cauterized and collapsed by stitching as with the Pribram method. Autopsy after eight

days showed marked peritonitis with leaking, necrotic gall-bladders in both. A cat which had a tube placed in the gall-bladder (removed the third day) showed, after eight days, an excellent result—apparent obliteration of the gall-bladder.

A summary of results with use of the actual cautery on the mucosa of the gall-bladder in twelve dogs and three cats reveals good recoveries, after six to eight days, in six dogs and one cat. There was liver damage in two dogs, peritonitis, after eight to twelve days, in three dogs and two cats, necrotic gall-bladders, after eight to twelve days, in six dogs and two cats. In general, light cauterization of the mucosa gave better results than heavy, but necrosis resulted even with that. Heavy cauterization produced liver damage. The difficulty with a hot iron is in limiting its action to the mucosa without causing too rapid necrosis of the gall-bladder or damage to the liver. The best results were obtained with gall-bladders rendered slightly sclerotic by previous mechanical damage.

THE USE OF THE HIGH FREQUENCY ELECTRIC CURRENT FOR OBLITERATION OF THE GALL-BLADDER

It is obvious from the foregoing experiments that the difficulty with the actual cautery is to control the degree of destruction of the tissues. The best results were obtained with light cauterization. The high frequency current from the electrosurgical unit allows much better adaptation. For these experiments the Bowie Unit, old style, was used.

The tissue dissolving current, the "cutting current", was employed with six dogs. The ball electrode with the power control set from fifteen to twenty-five, low voltage and light dehydration, was run around over the mucosa of the gall-bladder, a drainage tube then being placed inside. Generally too much tissue destruction was produced. Good results were obtained in three of the dogs, those in which light treatment to the mucosa was given. The other three had necrosis of the gall-bladder, and two of these, peritonitis.

In two dogs the gall-bladder was damaged previously by clamping over the surface, which resulted in considerable inflammatory thickening with adherent omentum. In both cases the mucosa was treated moderately with the cutting current. The gall-bladder was first split to the cystic duct which was tied with silk. The ball electrode was run over the mucosa and the gall-bladder collapsed with a continuous stitch, no drainage being employed. Autopsy after several weeks showed a good result in obliteration of the gall-bladder in one of the dogs, in the other it was only partly obliterated, having reformed somewhat from the cystic-duct end. This tissue-dissolving current, as well as the actual cautery, apparently worked better with thickened, inflammatory gall-bladders, but likewise

it seemed to be too difficult of control for safe use.

TREATMENT OF THE MUCOSA BY THE COAGULATING CURRENT

The method of Pribram was used with seven dogs, simply substituting the coagulating current (biterminal) from the electrosurgical unit for the actual cautery. The gall bladder was split to the cystic duct by using the cutting current, with heavy dehydration to help control hemorrhage. The spurting bleeders were snipped in the edge of the cut wall of the gall bladder and tied. The cystic duct was dissected free and tied. The mucosa was treated by fulguration (sparking) making occasional contact of the needle with the tissue. Treatment was rather thorough to prevent regeneration. Then according to Pribram's method the leaves of the gall bladder were sewn together and the cavity obliterated. No drainage was used.

Three of the seven dogs made good postoperative recoveries. One of them, sacrificed after four days, showed only slight sloughing of the gall bladder which probably would have been resolved. Another, sacrificed after two weeks, showed an excellent result, the remains of the gall bladder being fibrous and covered with omental adhesions. This is the ideal, and the best that can be expected after leaving so much dead tissue in place. The third dog was in excellent condition after two weeks.

In the other four of the seven dogs poor results were obtained. One of them died of peritonitis five days after the operation, three died of intraperitoneal hemorrhage, after one two and eight days respectively, two of them showed a sloughing gall bladder.

With two additional dogs the gall bladder was damaged by clamping nine days before the Pribram method was applied. Good results were obtained in both these animals, sacrificed after ten and eleven weeks. In one, however, the gall bladder had regenerated to about one-half its normal size, again emphasizing the necessity for complete destruction of the mucosa with this type of operation. In the other dog there were numerous adhesions of the omentum and adjacent viscera to the gall bladder fossa, this being the expected result.

It is to be noted that the use of fulguration upon the non sclerotic gall bladder is liable to result in hemorrhage. The probability is that the vessels are so little supported that they bleed when the charred tissue is dissolved. It will be remembered that with the sclerotic gall bladder the cutting or tissue-dissolving current was safer and more effective. The same is observed with the use of fulguration from the coagulating current.

In two dogs the uniterminal coagulating current (desiccation) was applied through the flat

blade electrode which was rubbed over the mucosa rather lightly, the gall bladder being sutured according to the regular Pribram procedure. Both these dogs died, one the same day, and the other after six days. Both showed hemorrhage into the peritoneal cavity, one of them bile leakage. Probably with the uniterminal current the tissue destruction is too great, weakening the walls of large vessels, or the depth of coagulation is not sufficient to seal off the vessels for a period long enough to allow a firm clot to form in them before the ends open.

MODIFIED PRIBRAM OPERATION, USING COAGULATING CURRENT (BITERMINAL)

Following these experiments, while observing a cholecystectomy at the Massachusetts Memorial Hospitals upon a chronically thickened and subacutely inflamed gall bladder I saw the surgeon, W. K. S. Thomas, split the vesicle to the cystic duct along the front with scissors, and then trim off the two leaves a short distance from their attachment to the liver, clamping and tying the bleeders encountered. This suggested a modification of the Pribram operation by removing the redundant parts of the gall bladder for the purpose of reducing the amount of dead tissue to be disposed of by autolysis.

In four dogs a combination of this method and that of Pribram using the electrosurgical unit, was tried. The gall bladder was split to the cystic duct using the cutting current, heavy dehydration, then the leaves of the gall bladder were cut away about one centimeter from the attachment to the liver, clamping and tying the bleeding vessels. The cystic duct was dissected free and tied. The mucosa of the part of the gall bladder left attached to the liver was thoroughly fulgurated with the coagulating current. In three of the four dogs the edges of this coagulated tissue were whipped over with a continuous stitch, no drainage was employed.

Two of the four dogs made good recoveries, one of these being the subject in which the gall bladder edges were not stitched after the coagulation. These two dogs were sacrificed after two months. In one of them the gall bladder had reformed to the size of a walnut, again emphasizing the necessity for tying the cystic duct low down and of being sure to kill all the mucosa of the gall bladder with the coagulating current. The dog in which the remainder of the gall bladder was not stitched after the coagulation showed an excellent result. The stomach at the pylorus, however, was fixed to the gall bladder fossa with pronounced adhesions. The two other dogs died the first day after the operation, from hemorrhage into the abdominal cavity. One of them showed a large clot of blood in the gall bladder fossa. Probably with some of the larger vessels the coagulum dissolved rapidly and allowed bleeding. This suggests that larger vessels should be tied and the tissue

about them should not be treated with fulguration

In three additional dogs the gall-bladder had been damaged previously, in one of them, nine days before the cholecystectomy, by clamping, and in the others, three months before the operation, by the application of ninety-five per cent phenol. In the first, the gall-bladder was acutely inflamed, and in the other two slightly sclerotic. At the operation the gall-bladder was split to the cystic duct with the cutting current, using heavy dehydration, the bleeders were clamped and tied. Then the redundant portions of the gall-bladder were cut away with the same current about a centimeter from the attachment to the liver, the bleeders again being clamped and tied. With the coagulating current, using *both fulguration and contact coagulation*, for thoroughness, the whole surface of the portion of the gall-bladder left attached to the liver was treated, *taking care to avoid the points where vessels were tied*. The dogs were sacrificed from two to six months after the operation, having been in perfect health and showing at autopsy only a few adhesions of omentum and duodenum to the gall-bladder fossa.

DISCUSSION

The object of this set of experiments was to develop a method whereby the risk of operation upon the acutely inflamed or sclerotic gall-bladder would be diminished. The chief danger in these cases is hemorrhage, which treatment with cautery or electrosurgery helps to control. It is reasonable to suppose that if hemorrhage could be prevented with the markedly diseased gall-bladder it would be with the less damaged vesicle, but this does not appear to be true. The coagulating current, which is best for controlling the hemorrhage in extremely vascular tissue, must be selectively used with the gall-bladder for the best results. For instance in treatment of thirteen non-sclerotic gall-bladders by the modified Pribram method, using the coagulating current, seven of the dogs died of hemorrhage from the operative site. Apparently the coagulated tissue of the vessel wall and that about it dissolved too rapidly. The uniterminal coagulating current is probably more offensive than the biterminal in this respect. It must be concluded that all the larger vessels should be ligated and the tissue in their immediate vicinity not coagulated.

Thorek⁹ has drawn a distinction between important types of electrocoagulation for cholecystectomy. Fulguration, or treatment by sparking without contact of the electrode, produces a more superficial, yet intense effect, resulting in carbonization. On the other hand, real electrocoagulation, obtained by inserting the needle into the tissue, or by holding a flat electrode in contact, leads to the formation of a

firm coagulum, which, though more effective in disposing of the gall-bladder with little disturbance to the patient, will not dissolve so readily and lead to secondary hemorrhage. Even so, it seems preferable to tie the large vessels rather than to treat them electrosurgically by any method.

In these experiments results with electric current of different types were all better in the sclerotic gall-bladder—of seven dogs, none died from hemorrhage.

CLINICAL EMPLOYMENT OF ELECTROSURGERY FOR CHOLECYSTECTOMY

Since experimental results indicated that treatment of the severely inflamed or sclerotic gall-bladder with the coagulating current was a safe procedure, and since in these cases dissection by the ordinary method is rather hazardous, it seemed that the clinical use of electrosurgical cholecystectomy in selected cases was warranted.

This was accordingly carried out by the following technique, which was an outgrowth of our experimental observations. "After carefully packing away other viscera and placing self-retaining retractors the gall-bladder is aspirated and split longitudinally to the cystic duct, or near it, using the cutting current with high dehydration. Fluid and stones are removed by the aspirator and spoon. Then by the same means the tissue of the gall-bladder is cut away at about a centimeter from its attachment to the liver, the bleeding vessels being snapped and tied. The section of gall-bladder adherent to liver is not removed, avoiding danger of serious hemorrhage there. This tissue is thoroughly coagulated and dehydrated by fulguration. If any considerable portion of mucosa is left it may regenerate, resulting in a persistent sinus. If the cystic duct can be readily located it is tied or drained as indicated, if not it is ignored. The region is well drained, omentum being packed in to protect other viscera and prevent crippling adhesions. Stones may be left behind, either in the cystic or common duct, but this is better than risking death of the patient or doing irreparable damage in attempts at their immediate removal, since they can be handled by a secondary operation after the acuteness of the disease has subsided. The chief advantage of the method, however, is that since the main infective focus is removed, secondary operations are less often required than after simple drainage of the inflamed viscus."¹⁰ Note the statement "this tissue is thoroughly coagulated and dehydrated by fulguration." The method employed was to treat the remaining tissue of the gall-bladder both by contact with the needle, and by sparking. This method was published before I learned of Thorek's work which took account of the difference between contact coagulation and fulguration. I am grateful to Thorek for the distinction, and wish to emphasize the

necessity for employing real contact coagulation in electrosurgical cholecystectomy. A second article dealing with results in clinical cases will be published later.

SUMMARY

1 The great advantage of electrosurgery is in control of hemorrhage. It has been shown by others that vascular tumors and organs, such as liver, kidney, and spleen, may be treated first by deep coagulation, and then removal with the cutting current, without hemorrhage. Our experiments have confirmed this finding: large sections of the liver having been removed safely in this way.

2 As an outgrowth of Pribram's "mukoklase" a method was tried for destruction of the gall bladder simply by canterization of the ovate duct. This proved to be unsatisfactory on account of bile leakage and sloughing of the gall bladder. Canterization of the whole mucosa by the Pribram method in the non sclerotic gall bladder was likewise unsatisfactory. In the sclerotic gall bladder it worked fairly well but we believe that any treatment of the gall bladder by the actual canter is too dangerous and difficult for general use.

3 The tissue-dissolving or "cutting current" was also too difficult of application for obliteration of the gall bladder. Its use for "mukoklase" was unsatisfactory in the non sclerotic gall bladder, the chief danger being hemorrhage. With the sclerotic gall bladder the results were better. However, it is not recommended.

4 The uniterminal coagulating current (desiccation) is too highly destructive of tissue and the effect too superficial, to be safe. In our experiments its use was followed by secondary hemorrhage.

5 The method of preference finally developed. Aspirate the gall bladder and split it

to the cystic duct with the cutting current. The duct is dissected free and tied. The leaves of the vesicle are then trimmed away about a centimeter from the attachment to the liver, clamping and tying the bleeding vessels. Then the section of gall bladder left attached to the liver is thoroughly treated with the coagulating current, by contact with the needle and fulguration, avoiding the points where the vessels are tied. The method of Thorek employing contact coagulation to considerable depth seems preferable to fulguration.

6 Drainage was not employed except in three of the experimental dogs. We have felt, however, that drainage is preferable in cases where there is considerable dead tissue to be absorbed. In the article* on clinical application of these experimental results (drainage being employed) the question will be discussed.

7 Electrosurgical cholecystectomy is best adapted to the markedly inflamed, or the sclerotic gall bladder.

ANTERIOR POLIOMYELITIS WITH REFERENCE TO THE OCCURRENCE OF TWO ATTACKS IN THE SAME INDIVIDUAL*

(With Report of Two Cases)

BY LOUIS COHEN, M.D.†

A SECOND attack of anterior poliomyelitis occurring in the same individual is very rare. To date there have been reported thirteen such proved cases. In over three thousand cases of anterior poliomyelitis seen in the Department of Orthopedic Surgery at the University Hospitals of the State University of Iowa there have been only two cases which have definitely represented a second attack of the disease.

From the Department of Orthopedic Surgery, State University of Iowa. Service of Dr. A. Steindler.
†Cohen, Louis—Intern, Orthopedic Service, State University of Iowa Hospital, Iowa City, Iowa. For record and address of author see "This Week's Issue," page 523.

Flexner, in his experiments on monkeys, could in no case produce a second attack of anterior poliomyelitis in an animal, once that animal had been infected and had survived. He injected the second dose of virus at intervals varying from eight days to four or five months after the onset of paralysis resulting from the first dose. In no instance was the monkey rendered ill or was there a recrudescence of the paralysis. He concluded that, "These results indicate what will probably be found to be equally true of human beings, that one undoubted attack of poliomyelitis even when unaccompanied by def-

nite paralysis, produces a state of refractoriness in reinoculation with active virus that endures for months and probably for years, if not throughout the life of the affected individual." He was also able to demonstrate by animal experiments that human beings who have been infected with anterior poliomyelitis and have survived contain in their blood for two or more years certain neutralizing principles for the virus causing the disease

comparatively not rare. The second group comprises those cases in which the second attack occurs two or more years following the first attack, and until now only thirteen such proved cases have been reported. Only the latter group of cases can be considered as representing a true second attack and the former is explained as follows

The immunity acquired by man as a result of one attack of anterior poliomyelitis occasionally

Case No	Date report Author	Sex	Age of Attacks	Interval between attacks	Parts affected

Lucas and Osgood, in 1913, reported a case illustrating a second attack of acute anterior poliomyelitis. Four months following the onset of this second attack the virus present in the nasal secretion of the patient was of such active virulence that when injected intracerebrally into a monkey it produced a typical and fatal attack of poliomyelitis in that animal. This is to be kept in mind when we consider that there are two groups of recurrence of anterior poliomyelitis which are definitely distinct from each other. One group comprises those cases in which the second attack occurs within four months after the first attack and which are

is slow in developing. The active virus may remain in the nasopharyngeal secretion of the individual for a period up to four months following an attack, as shown by Lucas and Osgood. Therefore, any relapse occurring within this period can be explained as an auto-infection of the individual by the active virus present in his own nasopharyngeal secretions, this occurring before the full development of immunity following the first attack. This does not, of course, completely eliminate the possibility that the second attack may be a reinfection from a new external source

When the interval between the two attacks

is two or more years the reinfection is undoubtedly a new one from an external source, as the active virus has experimentally never been found to be present in the nasopharyngeal secretion of a patient later than four months after the termination of the acute febrile stage of the disease in such virulence as to reproduce the disease in a monkey. There have been no cases of a second attack reported, whether it be a recrudescence or a reinfection, occurring in the interval between four months and two years every following the first attack.

It is thus logical to conclude that immunity to anterior poliomyelitis once it is fully developed, either as a result of an attack or a recur-

red attack, and that the right arm was not affected by the second attack.

His family history and marital history were non-contributory. His past history was also negative except as mentioned above.

His physical examination was negative except for the following:

He walked with the aid of a cane.

He had a moderate lordosis, ankle valgus on the left, equinus of the right foot, and two inches shortening in the right lower leg.

Reflexes	Patellar reflex reinforced	Rt. absent. Lt. slight.
	Tendo-Achilles reinforced	Rt. absent. Lt. slight.

Case No.	Date report Author	Sex	Age of Attacks	Interval between attacks	Parts affected
14.	Cohen 1935	M	1) 6 yrs. 2) 31 yrs.	25 yrs.	1) rt. arm rt. leg 2) lt. arm rt. leg weak
15	Cohen 1935	F	1) 12 yrs. 2) 30 yrs.	18 yrs.	1) rt. arm lowers 2) arms, legs trunk

descence of an initial attack, is absolute only up to a period of two years.

The thirteen proved cases of reinfection with anterior poliomyelitis in the literature are shown in the large table, taken from Quigley¹⁷ and Stull.¹⁸

In no case was there reported a complete recovery following the first attack.

To the table, reporting cases 1 to 13 inclusive must also be added the author's two cases.

The following are the two cases seen in this clinic:

CASE 1

H. L. D., a thirty-one year old married white male, came to the Out Patient Clinic on January 5, 1934 complaining of general debility and weakness in the region of the left hip both of four months duration. He stated that he had had infantile paralysis involving the right arm and right leg in 1908 and had, at that time, remained off his feet for one year following which he used crutches for one year. The disease was epidemic at that time. Following this he improved. He retained some residual paralysis but has been able to get about with out the aid of a cane or crutches. He worked in a garage and could do a full day's work easily until September 2, 1933, when he had what was diagnosed as a gall bladder infection and was put to bed for three days. When he got up his legs and arms were so weak that it was necessary for him to go to bed again and remain there for two weeks. He had difficulty in moving his arms and legs. He had pain in his neck and back, ached all over and had some elevation in temperature did not eat well for one week, but did not vomit. His strength has gradually returned but he is still unable to walk without the aid of a cane.

He states very definitely that the left arm was not affected by the first attack and that the right leg is now somewhat weaker than before the sec-

ond attack.

Sensations were normal. The muscles of the left leg were normal. There was practically complete paralysis of all the muscles of the right leg and there was marked atrophy of both the right thigh and calf. There was a moderate lordosis and a positive Trendelenburg test on the right.

The muscles of the upper arm showed considerable paralysis bilaterally; those of the lower arm were unaffected.

In this patient an arthrodesis of the right shoulder was indicated. He did not desire an operation and was discharged until such time as he might consent to one.

CASE 2

E. K., a thirty-year old white married female entered the hospital because of inability to use the right arm and both legs. She was seen in the orthopedic Out Patient Clinic on January 7, 1935. She states that she was perfectly well until November 4, 1934 except for a very slight sore throat during the three to four days preceding that date. On the following afternoon (Monday) her right shoulder ached and her neck was stiff. She had no fever and continued with her usual activities. On the next day (Tuesday) her legs began to ache. On the following day (Wednesday) her "right arm became completely paralyzed." The legs continued to ache and were "weak" but she was able to be up and continue with many of her usual activities. She called an osteopath that night who told her that she had "neuritis" and gave her a salve. She remained in bed and the next night she called a physician who told her she had "infantile paralysis" (Thursday November 8).

Her physician states that she then had a temperature of 104, pulse 136. He further states, "There was practically a complete paralysis of the right arm and a general weakness of the left arm and both legs. The reflexes were absent or very weak."

Two days later her legs became completely par-

alyzed. She could, however, move her feet. Two to three days later the left arm became paralyzed. She remained in bed for three weeks. During this period the pain in the right shoulder was at times severe enough to require codeine for relief and the pain in the legs gradually disappeared. She has had no pain since then. The left arm improved considerably during the first week and has been improving gradually since then so that she could, on admission, practically feed herself. The right arm remained about the same until two weeks before admission since which time it has improved only slightly. The right leg has improved to about the same degree as the right arm. The left leg has shown no improvement.

During the three weeks prior to admission she also received some massage.

She was admitted to the neurological service on January 3, 1935. There lumbar punctures were done, a diagnosis of anterior poliomyelitis was made, and she was referred to the orthopedic service.

She knows of no other case of anterior poliomyelitis in her neighborhood.

At no time did she receive serum.

She states that she had infantile paralysis eighteen years ago (October, 1916), with involvement of both legs and her right arm. This is corroborated by the physician who treated her at that time. "She could not lift her right arm or right leg off the bed, and could barely raise the left leg." There were two other cases in the immediate neighborhood. She received no serum.

At present her main disability is inability to use the right arm and both legs.

Marital history, family history and past history are non-contributory except as mentioned above.

Physical examination revealed a young female whose only positive findings were as follows:

The knee jerks, ankle jerks, and biceps, triceps and radial periosteal reflexes were absent bilaterally.

The right arm and both legs were almost totally paralyzed. The left arm also showed marked involvement of a considerable number of muscles. There was also a marked involvement of the trunk.

This patient has been receiving bed rest and physical therapy, also splints to prevent the development of deformities.

The interval between the two attacks in the first case here reported was twenty-five years. The recovery following the first attack was incomplete. Although the right leg, in which there was a residual paralysis following the first attack, became somewhat weaker following the second attack, the part affected most in the course of this second attack was the left upper arm, which had not been affected in the first attack. Thus we see that, except for the fact that the interval between the two attacks in this case was longer than the interval in any of the other cases reported, it presents no feature unusual to them.

The second case here reported does, in some respects, differ from any of the other cases reported. First, there was a more extensive involvement as a result of the first attack than in any of the other cases, i.e., total paralysis of two extremities and almost total paralysis of a third. Secondly, in no other case was there a

complete recovery following the first attack. Thirdly, the three extremities which were affected as a result of the first attack were affected to practically the same degree during the course of the second attack. The fourth extremity, i.e., the left arm, which was also completely paralyzed during the course of the second attack and which was not affected during the first attack, is the only one which has recovered to any appreciable degree.

CONCLUSIONS

1 It has been impossible to produce a second attack of acute anterior poliomyelitis in monkeys. It is thought that one attack confers upon them a lasting immunity to the disease.

2 There are two groups of recurrence of anterior poliomyelitis in man which are definitely distinct from each other. One group is due to a recrudescence of the infection, occurs within four months of the first attack, is not rare, and is not a true reinfection. The second group is a true reinfection, occurs two or more years after the first attack, and is rare.

3 Immunity to anterior poliomyelitis, once it is fully developed, is absolute only up to a period of two years.

4 Two cases are reported here, one of which presents unusual features.

TORSION OF THE PREGNANT UTERUS

Report of Two Cases

BY HILBERT F. DAY, M.D.*

TORSION of a pregnant uterus is undoubtedly a rare and may cause a real surgical emergency. It is my object in the following pages to bring the literature up to date and to report two personal cases.

A study of the literature shows that the largest number of cases reported have been by French and German physicians rather than in English periodicals. I have found that the most satisfactory English article on the subject is that by Robinson and Drvall, published in 1931 in the *Journal of Obstetrics and Gynecology* of the British Empire. Their review is so complete and their abstracts of twenty five cases by other writers so satisfactory that there is no reason for the writer to review the articles they have abstracted. Therefore, I am accepting their bibliography of fifty two references and adding to it about thirty new references with abstracts of twelve.

General Statement. Torsion of the pregnant uterus has for many years been reported in journals having to do with veterinary obstetrics and is not a too rare complication of a cow's labor. In the human being it has been more recently reported and is far more rare. Many writers in speaking of torsion of the uterus have described the mechanics underlying this accident and have reported some cases which seemed to have occurred in a normal uterus, but from my experience and from examining the literature I am inclined to feel that the uterus does not become twisted unless there is some abnormality in it. Symptoms may be absent, slight, or very acute, according to the rapidity with which the torsion occurs. Unquestionably, the most common causes of torsion of a pregnant uterus are the following:

- 1 A fibroid or fibroids.
- 2 An ovarian tumor.
- 3 The gradual contraction of a chronic inflammatory process on either side of the uterus.
- 4 Postoperative scar contraction.
- 5 A combination of the above causes.

Practically all of the cases the author has been able to review have shown torsion toward the right. It is difficult to state what starts torsion in these cases, for the history of most of the cases does not give this. Some authors think that the twisting from left to right is more common because of the fact that the descending colon fairly well fills the space on the left side.

It is possible to conceive that some sudden movement in a case which has one of the predisposing causes might start the rotation. In one of the author's cases, it followed a too long automobile ride.

Diagnosis. In practically none of the cases described in the literature was the diagnosis of torsion of a pregnant uterus made before operation or death. Truly this rare disease has no single characteristic symptom on which to base a competent diagnosis. The surgeon who knows of this condition should at least consider it among others when he has to treat a pregnant woman, suffering from an acute abdominal crisis, whose condition is obscure. To make such a diagnosis, there should be a careful general history, menstrual history, description of recent symptoms, a complete general physical examination, including rectal examination, and ordinary laboratory findings, particularly a white count. Most important of all is a painstaking gentle abdominal examination.

History. The chief symptoms which recur often in the cases reported in the literature are the following:

1 Abdominal pain

- a Gradual onset increasing to such severity that only a large dose of morphia will relieve it.
- b Sudden pain most generally localized on the right side of the abdomen which may be so severe that only a large dose of morphia will give any relief.

2 Shock

In some cases the shock is so severe as to cause collapse. It is very difficult to differentiate this and shock of a sudden peritonitis or a partially separated placenta.

3 Abnormal findings

- a The uterus may seem of atypical shape. For instance a large fibroid on the side may feel like an additional fetal head when partially obscured by a very tense abdomen.
- b The abdomen has not the ordinary resistance of general peritonitis, but is extremely tense. Tenderness is not uniform over the abdomen, but is more marked above the pubes and on the side toward which the torsion has occurred. With the administration of a little ether the signs of collapse recede and the abdominal spasm dis-

*Day Hilbert F.—Professor of Clinical Surgery, Tufts College Medical School. For record and address of author see "This Week's Issue," page 672.

appears. Then the uterus and possible fibroid can more easily be defined.

4 No external hemorrhage

Practically nobody has reported any vaginal bleeding in these cases. Occasionally there has been found some internal hemorrhage.

5 Tenderness on rectal examination

- a Generally, a hard cervix is felt with tenderness in the vault
- b All necessary information can be obtained by a rectal examination
- c The author thinks that cases revealing the above recorded symptomatology should not have a vaginal examination because of the probability of a laparotomy and the possibility of either carrying infection up into the vaginal canal or stimulating labor by examination of the cervix.

Treatment The author believes that manipulation in an attempt to reduce torsion is usually unsuccessful and therefore unwarranted and that operative interference should be resorted to as speedily as possible. As said before, the condition of shock seems to be relieved as soon as the anesthetic is started and he believes that the cause of a torsion can only be relieved surgically. What can be or should be done at the time of operation can only be determined by what the operator finds. If it is possible to do myomectomies and then reduce the torsion as in one author's cases, that method should be practiced. It may be necessary besides this to do a hysterotomy or section, a hysterectomy if the uterus does not seem to be viable.

The above statement that manipulation is unwarranted, is not absolute as is shown by the following case.

Dr David Rose, of Cambridge, told me that he was called to see a woman at the end of the first stage of labor, who was suddenly seized with a severe abdominal pain and was in beginning shock. The doctor who was attending her told him that during her pregnancy he had noticed a fibroid on the left side of her uterus. On examination, Dr Rose found this fibroid on the right side and by manipulation was able to shift it back to its original position. The patient's pain disappeared and she delivered spontaneously a few minutes later. This undoubtedly was another case of torsion of the pregnant uterus in its initial stage.

REPORT OF AUTHOR'S CASES

In the following paragraphs, I wish to describe two personal cases of torsion of a pregnant uterus. The first case presented no problem but proved to be a curiosity. The second case presented a very difficult diagnostic prob-

lem and entailed a moderately serious operation. The twisting of the uterus generally takes place from left to right, as it did in both of my cases. The most common cause of such twisting is due to a tumor attached to the fundus of the uterus.

CASE 1 Mrs M C was operated on January 6, 1922 at a small hospital in the suburbs of Boston. She was a twenty two year old Jewess, 4 ft. 10 in tall, weighing 105 lbs, who had never had any menstrual disorder. She had been married three years. She had a justo-minor pelvis and had been previously delivered by Caesarean section in a Boston hospital after fourteen hours of ineffectual labor. The baby of that delivery died at the hospital.

Despite her previous Caesarean section and the fact that her measurements were so low as to be absolute indications for delivery from above, plus a good sized baby in this pregnancy, she was allowed to have twenty four hours of labor and, previous to my seeing her, had had a vaginal examination.

OPERATION Perpendicular abdominal incision to left of umbilicus four inches long, two-thirds below the level of the umbilicus. Abdomen opened, uterus inspected and the scar of the previous Caesarean section could not be found, but a tube and ovary were seen slightly to the right side of the midline of the uterus. The uterus was of normal color and it was impossible to rotate it one way or the other, and, therefore, although I suspected that the posterior surface of the uterus was presenting, I opened it through that surface and delivered a healthy seven pound boy. The uterine wall was closed in three layers after the delivery of the placenta. Then on examination after some shutting down of the empty uterus, I found that there was a firm band of scar tissue from the anterior surface of the uterus to a point low down in the right pelvis. This I separated between clamps and tied off, and then discovered that the torsion of the uterus had been caused by a large ovarian cyst which had fallen into the pelvis. This tumor was removed. (The histological examination reported by Dr William A Hinton of the Harvard Medical School was as follows: "Histologic examination shows tissue of mesothelial origin presenting no evidence of malignancy.") After the removal of the band and tumor, the uterus returned to a normal position, rotating from right to left side. My line of uterine sutures entirely disappeared as they were through the posterior surface of the uterus. This patient's puerperium was normal. The patient was examined two months later by me and was found to have a strong scar and to be in excellent physical condition.

CASE 2 Mrs C was seen in consultation in a hospital during August, 1933 at the request of Dr S M. As the patient was in considerable shock, the following history was obtained from him and the patient's husband. She had been married three years and had had no pregnancies, and during that period had led a very active life. In the past month she and her husband had taken an automobile trip in Nova Scotia. She was perfectly well up to four days previously, when she had some abdominal pain and consulted a doctor in St John, N B, who advised her to get home quickly. Following his advice, she returned by the next boat instead of driving down. Immediately on getting home she called a doctor who found her in bed complaining of such severe abdominal pain that he gave her $\frac{1}{2}$ gr of morphine. This doctor reported to the physician with whom I saw her that at the time of his examination the abdomen was fairly soft, but that he felt a larger mass slightly above the level of the umbilicus on the right side. He described it as a tumor the

size of a full term baby's head. He said he thought of pregnancy particularly because the patient's husband said that he thought his wife's last period was about four months ago but that he did not find any signs in the breasts to substantiate this idea. He made no vaginal examination. The next day Dr S. M. saw her and, finding her in a serious condition, took her immediately to a hospital where I examined her with him.

When I examined the patient in the hospital I found a woman in shock who looked very sick and was actively nauseated. Quite evidently she was suffering considerable abdominal pain particularly in the lower abdomen. She complained considerably of this pain and said that it was much worse if she had to lie on her back therefore she preferred to lie on her right side. Her temperature was 98.4 her pulse 120 of rather poor quality her leucocyte count was 20,000, systolic blood pressure was 102. A catheter specimen of urine was found to be normal.

The patient was a well-developed and nourished woman weighing 145 lbs. and was 5 ft. 8 in. tall, blonde type. Eyes ears throat normal. Tongue was slightly coated. Heart area normal, action regular rapid with no murmurs. The lungs were clear. Breasts seemed to me to be slightly enlarged and to suggest pregnancy although no fluid could be expressed from the nipples. The abdomen was distended throughout, rigid, tense and tender and there was a suggestion of a mass to be felt in the right upper quadrant. A pelvic rectal examination revealed a slightly softened cervix with a tender mass in the posterior culdesac.

Because of the patient's general condition and the above findings it was decided that she had an abdominal condition warranting immediate surgical intervention.

Preoperative diagnoses

- Pregnancy plus ovarian cyst with twisted pedicle.
- Pregnancy plus fibroid with twisted pedicle.
- Extra uterine pregnancy ??

OPERATION Patient was given morphine grs 1/4 and atropine grs 1/100 immediately and taken to the operating room after emergency preparation. In the operating room the patient was given ether anesthesia and as is the case in so many patients in shock as soon as she became anesthetized the condition of her pulse improved and the abdominal spasm let up. We were then able to palpate the abdomen and we felt a large mass on the right side slightly above the level of the umbilicus which we had been unable to feel definitely with the abdomen rigid. Either iodine alcohol preparation to skin. An incision about 8 inches long was made running from pubes upward to 1½ inches above the umbilicus slightly to right of midline. On opening the abdomen, there was an escape of considerable abnormal straw-colored fluid. The examining hand showed that the mass previously felt was a fibroid tumor as large as a coconut, intimately connected with the uterus, not really pedunculated although the base was about one-half the size of a cross section of the tumor. The uterus itself was found to be about the size of a four months pregnancy and the uterine muscle seemed slightly darker than normal in color. On careful examination it was found that the fundus was twisted halfway about to the right, and that, when this was corrected the fibroid described above had risen from the left side of the uterus. The mass previously felt by pelvic examination in the posterior culdesac was another fibroid about the size of a navel orange attached to the uterus which had been forced down into the pelvis when the uterus was twisted to the right. It was undoubtedly an additional cause for the patient's pain. After short deliberation it seemed

best to try to do myomectomies rather than a hysterectomy. The large fibroid was removed first. In so doing we cut down almost to the endometrium and there was considerable difficulty in sewing up the large defect. Three layers of sutures were employed and the bleeding finally controlled. The first two layers of sutures were continuous the last ones were interrupted figure of eight sutures. No 2 chromic catgut being used. The smaller fibroid from behind the uterus was removed in the same manner. After the removal of the tumors we kept the uterus under observation for about ten minutes to see whether there would be any serious bleeding. There was some oozing but as it seemed to be gradually diminishing we decided to close the abdomen. The abdominal wall was closed in layers in the usual manner. Patient left the operating room in fair condition. (The pathological report of the tumors removed was "leiomyomata.") For the first four or five days postoperatively the patient was kept absolutely quiet with morphine. After that, narcotics were omitted and the patient made an uneventful hospital convalescence. The abdominal wound healed by first intention and the patient was out of bed on the thirteenth day. On this day she first felt life.

Before the patient left the hospital she was advised to return for Caesarean section in January. That type of delivery was recommended because of the fear that large defects in the uterine wall repaired during a well-advanced pregnancy might leave a weak place in the uterus with the possibility of rupture during active labor.

On January 10 1934 a classical Caesarean section was performed and a large, healthy male baby weighing 7 lbs. 14 oz. was delivered. When the abdomen was opened some omental adhesions were found at the site of the myomectomy scar on the left side of the fundus, but the scar itself seemed fairly strong. The postoperative course following this Caesarean section was essentially normal the only variation being a rather sharp postoperative hemorrhage about ten hours after delivery.

I believe the two cases reported above are of interest. Both are cases of torsion of the uterus from left to right. The first one apparently occurred so gradually as not to have caused pain and the second so rapidly as to have caused very severe pain. I also believe that in the second case if it had been impossible for me to control hemorrhage after the myomectomies an emptying of the uterus by section plus myomectomies should have been considered rather than a hysterectomy since the uterus was evidently viable.

Myome roux à évolution rapide avec torsion axiale de l'utérus dans les suites de couches.
Trilist's case: A twenty-three year old woman with torsion of the uterus occurring three days after delivery. At operation, no tumor found. Subtotal hysterectomy performed. Recovery.
- Same DuRoi: No. 5 October 1932. P. 574.
Torsion d'un volumineux fibrome au cours de la grossesse.
L.M. Hamant et Hartmann.
Andre's case: A sixty-seven year old woman always regular examined 1931 before her marriage and found normal. Period Feb. early 14. In March had some pain. Operation in April. Fibroid tumor found turning to the right. Myomectomy and interruption of pregnancy. Stormy convalescence. Final recovery.
- Brussels Medical Journal. De Neve and Ingelsbrecht. September 1931.
Pedunculated Fibroid During Pregnancy: A twenty-seven year old woman, pains in stomach, two normal deliveries before. Last period May 15 that is, four months before. For four days pain in the flank. Mass in hypogastric pain on pressure. Dry aft. r. admission operation. Scarred fluid in the abdomen, peritoneal reaction. Fibroid size of new-born child's head from anterior surface of the uterus. Found behind the uterus. Myomectomy. Recovery. Subsequent normal delivery.

- 3 They may occur as often after spinal as after inhalation anesthesia
- 4 Long operations tend to increase the incidence of severe gas pains
- 5 Gas pains are only slightly more common after upper abdominal than after lower abdominal operations
- 6 Gas pains are not infrequent following hernia operations
- 7 Long preoperative hospitalization does not reduce the incidence of gas pains
- 8 Manipulative trauma plays an important rôle in the production of gas pains
- 9 The nervous type of patient is much more likely to have gas pains than the phlegmatic type
- 10 Gas pains can be greatly reduced by giving no fluids by mouth for twenty-four to forty-eight hours following any laparotomy
- 11 It is felt, by way of conclusion, that routine postoperative treatment should be abandoned

If the surgeon is aware of the relative importance of the various factors contributing to gas pains, it may be possible for him so to individualize his postoperative treatment as to have a minimum of gas pains

INCARCERATED BLADDER IN A SCROTAL HERNIA

Case Report

BY FRANCIS J. PETRONE, M.D.,* AND EDWIN VIEIRA, M.D.*

BLADDER herniations are relatively frequent, incarcerations less frequent, but incarcerations in the scrotum are found to be very rare. Because of the scarcity of such cases reviewed in the literature, a report of a case recently observed is hereby submitted for record with a survey of vesical hernias.

Vesical hernias are not uncommon as has been revealed by Erdman when he collected 8600 cases of hernias of various types and found that in four cases out of every thousand the bladder was involved in the hernia. Scrotal vesical hernias are however, rare, as Makkas in 1933 stated in a report of a case of a large bladder hernia on the right side. Quivy and Yvon also reported such a case in 1934. These workers were fortunate in making a diagnosis by cystogram, showing the greater portion of the bladder in the right scrotal sac. The anamnesis in their case revealed that the patient had a hernia since the age of fifteen, and that in later years he noticed that he began to urinate in two stages, first normally, and finally by manipulating the scrotum. Pfizner in 1930 reported a right irreducible hernia in the scrotum. The bladder was freed and returned to the abdomen and the hernia repaired in the usual manner.

Bladder herniations as already stated are not uncommon. In 1923, 406 cases were collected

from the literature and it was found that they occur twice as frequently in men as in women. In 359 cases 130 were on the right side 103 were on the left side, five were bilateral, and forty-two were not specified as to side. Femoral vesical hernias were included in the series, forty three were on the right and twenty-one on the left side, two bilateral and thirteen were not classified as to side. Other varieties of vesical hernias occurred, such as perineal, sciatic, ventral, and obturator, these types were however, very rare.

Preoperative diagnosis of bladder hernia is very low. In 347 cases the diagnosis before operation was made in only twenty-five cases, 279 were diagnosed during operation and forty-three recognized after operation. It has been noted that injuries to the bladder during the operation seem to be a very frequent incident. In 406 cases of vesical hernias 194 were injured during operation, nearly 50 per cent. This complication naturally aggravates the condition, especially if not recognized during the operation. Resultant fistulas lasted from one day to one year or more. The mortality has been found to be higher in those cases in which injury was not recognized during the operation.

REPORT OF CASE

Chief Complaint Pain in the right lower quadrant for the last six hours radiating to the groin.
Family History One son and one brother have large inguinal hernias.

*Petrone Francis J.—Assistant Surgeon Union Hospital and General Hospital Fall River Mass. Vieira Edwin—Externe Medical Service O. P. D. Rhode Island Hospital, Providence R. I. For records and addresses of authors see This Week's Issue page 632.

Past History Patient has enjoyed good health for the past twenty years. Has no history of serious ailments, accidents or operations.

Present Illness The patient was perfectly well up to the onset of his present condition at 8 A.M. He got up and was doing chores about the house when he noticed severe lancinating pains in the right lower quadrant which radiated down to the right groin. Severity of the pain became worse until he was obliged to call his physician for relief. The patient noticed that he had been constipated the last few days consequently took an enema without effect save for the passage of some gas. He had noted some difficulty in passing urine but never any retention requiring catheterization, nor has he had dysuria or passed blood. With the onset of the present condition a lump appeared in the right groin and gradually became larger. This swelling was in the right scrotal sac. It was tender to palpation and non-reducible. This lump had appeared in the past without symptoms and was always readily reduced on pressure.

PHYSICAL EXAMINATION

The patient was a large framed, obese Portuguese farmer weighing about 200 lbs. In evident distress with pain ruddy faced but slightly cyanotic and dyspneic. Temp 99 pulse 55 resp 20 W B C. was 15,000 and the differential showed 80 per cent polys. The Wassermann test was negative and urine analysis showed a slight trace of albumin a few leucocytes a rare hyaline cast and rare red blood cells. The tongue was heavily coated, mouth hygiene was poor and the throat was injected. The chest was barrel shaped excursions small but equal. The lungs showed the presence of sibilant rales throughout, with increased resonance and diminished breath sounds. Heart sounds were snoring in quality a soft systolic murmur at the apex was heard but not transmitted. A2 was accentuated. B P 210/100. Abdomen obese. A large swelling the size of a small grapefruit was noted in the right inguinal area extending down to the right scrotum. This mass had the feeling and resiliency of a tennis ball, and was very tender to palpation. The right lower rectus was rigid. The extremities showed no edema or deformities. Reflexes were normal. Patient was admitted to the R. I. Homeopathic Hospital September 15 1931 and was operated on the same day.

Preoperative Diagnosis Incarcerated Inguinal Hernia. (Right.)

OPERATION The patient was not considered a good surgical risk but surgical intervention was deemed imperative and avertin anesthesia supplemented with ether was used. In ten degrees Trendelenburg position the operative field was prepared with hexaevetol iodine. A four inch long incision was made one inch above Poupart's ligament down to the pubic spine over the mass. This mass was located inside the scrotum and outside the external abdominal inguinal ring. The primary incision extended down to the external oblique fascia. All bleeding points were clamped and tied. A marked constriction band was cut just outside the external inguinal ring and when this was done the sac which was the size of a large orange collapsed. The cord was isolated from the sac to which it was firmly bound by adhesions. The sac was peculiar baggy and felt as though its contents consisted of omentum firmly adherent to the sac. This sac came di-

rectly out at the abdomen and did not follow the cord up the inguinal canal. It emerged from Hesselbach's triangle down through the external ring. By gentle dissection an attempt was made to get to the inside of the sac. It was disappointing to find that the bladder had been exposed and opened evacuating about four ounces of clear straw-colored fluid. It was realized that this was an unusual case of incarceration involving the bladder in the right scrotum. The bladder was immediately sutured with catgut. The redundant sac or flaps were clamped ligated and cut. The bladder was then pushed into place behind the pubis and several interrupted chromic catgut sutures placed from the conjoined tendon to Poupart's ligament. The external oblique fascia was sutured with continuous chromic catgut and the skin sutured with interrupted silk-worm catgut. A dry sterile dressing was applied and a retention catheter was placed in the bladder for continuous drainage. The patient took anesthesia very well except for moderate cyanosis at various intervals and the general condition at the end of the operation was considered fair.

Postoperative Diagnosis Incarcerated Scrotal Hernia at the Bladder (Direct Right)

Progress in the Hospital On the fifth postoperative day the retention catheter was removed and he began to void voluntarily but with some pain which gradually cleared up during the next few days. His urinary output increased his appetite was good his abdomen was soft and elimination was satisfactory. For several days he was troubled with general urticarial eruption. This was felt to be due to a throat infection as the urticaria cleared up when the throat improved. He was discharged from the hospital October 2 1931 improved. The patient urinated in normal amounts without pain and stated he was feeling well.

Pathological Diagnosis Hernial sac with intussusception

X-Ray Report of Bladder Cystogram showed a large filling defect of the right side of the bladder which diminished the capacity of the bladder to less than one-half. The defect was probably due to the repair of the hernia of the bladder into the scrotum. No part of the organ protruded below Poupart's ligament.

Progress of the Case Since Hospital Discharge Examination at patient six months after discharge shows a well healed right inguinal incisional wound with no recurrence of hernia. Patient has had no urinary symptoms of frequency or dysuria. He is feeling well and doing work about his farm.

COMMENT AND SUMMARY

From a survey of the literature incarceration of a bladder hernia into the scrotum is rare, while at the same time herniation of the bladder in various positions is not an uncommon finding in lower abdominal hernias. In conclusion it is obvious that in repairing any hernia in the lower abdominal region the bladder should be constantly kept in mind. Injuries to the bladder in these cases are too frequent a complication and are not even recognized at the time of operation. More attention should be paid to the history and particularly to the genitourinary aspect of the history. Whenever suspicions or

doubtful as to the presence of this complication the bladder should be catheterized and a cystogram made

THE ARTERIOGRAPHIC COMPARISON OF THROMBO-ANGIITIS OBLITERANS AND ARTERIOSCLEROSIS*

BY EDWARD ALLEN EDWARDS, M D †

THE arteriogram of normal arteries shows three characteristics which are changed in both arteriosclerosis and in thrombo-angitis obliterans. These characteristics of normal arteries have been noted by Allen and Camp as follows: first, the smooth and uninterrupted contour of their lumens, secondly, the direct course of the vessels, thirdly, the presence of no more than a minimum of collateral circulation¹

Examination of arteriograms of diseased arteries show striking deviations from the normal. In both Buerger's disease and in arteriosclerosis one finds varying degrees of blockage of the lumen, tortuosity of the entire vessel, and an increase in the number and size of the collaterals. I have observed, however, in common with Leriche, Fontaine, and Friehe², and with Sgalitzer, that one can nevertheless distinguish between the pictures of the two conditions.

The arteriosclerotic vessel (figure 1) may show not only abrupt blockage of the lumen, but also multiple eccentric rounded filling defects in the segments of the artery above the blocked portion. This gives a serpiginous outline to the image of the vessel lumen. Secondly, the lesser arteries and sometimes the main artery may be irregular or tortuous in their course. Thirdly, the number of collaterals are markedly increased.

The arteriogram in Buerger's disease is a different one (figure 2). The totally blocked areas of lumen are usually more extensive. Above these totally blocked areas one usually finds a lumen of smooth outline, with absence of the eccentric filling defects noted in arteriosclerosis. Secondly, the arteries are less apt to be tortuous. Thirdly, the visualized collaterals are fewer in number than in the arteriosclerotic.

The difference between the irregular lumen of arteriosclerosis and the smooth appearing lumen of Buerger's disease, can be explained by the occurrence of localized atheromata in the former disease, and their absence, in uncomplicated cases, in the latter. While discrete areas of proliferative thickening of the vessel wall may

occur in Buerger's disease, the process is more apt to be one involving the entire circumference of the lumen, giving the lumen a reduced but regular outline.

Furthermore, we know from clinical and post-mortem observations that the blood stream tolerates localized atheromata well, thrombosis occurring late in arteriosclerosis. In thrombo-angitis, however, even a small extent of involvement is quickly followed by thrombosis. In this way the arteriogram of an arteriosclerotic vessel may show atheromatous changes in outline, with or without occlusion, whereas in Buerger's disease it is almost an "all or none" proposition, i.e., as soon as the artery is involved more than a very little, it is apt to be thrombosed, and show abrupt loss of its lumen up to the normal part of the artery.

Concerning the fewer collaterals in thrombo-angitis, it is possible that it is to some extent a matter of time. That is, if the duration of the process were as long as in the arteriosclerotic, the collaterals might gradually develop to the same extent.

Previous work by Lewis and Reichert³, and by Horton⁴, indicated that the collateral circulation is much richer in thrombo-angitis obliterans than in arteriosclerosis. This finding is contrary to that of Leriche, Fontaine and Friehe, and to my own findings. I believe the conclusions of the former observers are open to question because their arteriograms were made from amputated limbs, while those of Leriche, Fontaine, and Friehe, and of mine, have been made during life.

CONCLUSIONS

The arteriograms of arteries injected during life show characteristics which are seemingly distinct for arteriosclerosis and for thrombo-angitis obliterans. In arteriosclerosis the arteriogram may show complete occlusion of segments but in addition shows eccentric filling defects in the other segments. They may also show a more tortuous course than normally, and the collateral circulation is greatly increased.

In thrombo-angitis obliterans the arteriogram shows a varying extent of thrombosis, with smooth-walled segments above the occluded segments. The course of the vessels is less likely

ALLERGY TO LIFE AN INTERPRETATION OF NEUROTIC CONSTITUTION*

BY ELLI MOSCHCOWITZ, M.D.†

DISPASSIONATE observers are fully aware that the neuroses are not only distressingly abundant, but that they are increasing in the United States. This, in itself, although serious, is made more alarming because certain common, sometimes fatal, maladies which I believe are in whole or in part of psychogenic origin, are increasing with prodigious speed. I refer especially to hypertensive disease, Graves' syndrome and gastric ulcer. We cannot flatter ourselves that all this increase is only apparent and that it is due to finer precision in diagnosis.

It is agreed that a neurosis is the result of a conflict between the environment and the individual and that it represents in a large measure failure to achieve the security for life or the satisfaction of the lust for power or of love, that is instinctive in human kind. Nor morality of conduct and behavior may be defined as an equation in which the forces of the environment are in delicate balance with the forces within the individual. The determination of the cause of the increase of neurotic illnesses therefore depends upon the answers to the questions as to whether the environment has become more onerous or the individual more sensitive or both.

It would be idle to deny that our environment has grown more onerous. It did not require an economic depression to make this apparent. Long before this event, life was becoming increasingly complex and was attended by a swiftness of pace so great that the human mind and frame were finding it difficult to keep in adjustment.

It is beyond my purpose and capacity to analyze completely the forces that made up the complex of our modern swift-paced civilization. Briefly as I see it, these forces are in some measure economic but for the greater part are psychologic. The unequal and unjust distribution of wealth is but one of the economic forces involved. Sufficient recognition has not been given to the fact that the progress of civilization has brought in its train a host of evils. If

one looks into the month of the gift horse of progress one finds that this progress has been material rather than spiritual, that it consists for the most part in inventions that enable us to do two things where we could do only one before, so that the life pattern has become more compact, a person today lives two lives within the space of one.

Of greater import, I believe, in the increased production of conflict is the enhanced sensitivity of the individual to life and it is to the analysis of this influence that I now turn.

The most important as well as the earliest influence which sensitizes the individual is the family, and of this hierarchy the mother is the most dominating member. One of the important contributions of the Freudian psychology has been the study of the effect of maternal influences on human behavior. The emphasis that has been placed on the so-called mother complex, whether it is hate or love, and its effect upon the sex life of the individual is hardly exaggerated. The range of influence is far wider than upon sexuality. Other instincts and senses may be affected and through these conduct and behavior.

The mother exerts the devastating influence which, to a large extent, sensitizes the individual by the mechanism of overprotection. Overprotection does less harm when the mother's fears are against physical insult or illness, but it is bad enough here because it may create the habit of introspection. The tragedy is when there is an overmastering fear of self-determination, which from birth begins a desperate mental moulding, a mental transference that is unrelaxing. It is because of the fear of self-determination that some mothers cultivate within the child an absolute dependence for every decision, no matter how trivial, and so the child reaches the years of discretion unable to meet the ordinary stresses of life. Such children remain infantile and their subsequent existence becomes a series of desperate attempts to escape realities. Mother love in its highest ecstasy can blight or even crush the human soul with a cruelty akin to that of the Inquisition. And the irony of it is that this is all done in blissful innocence and with intentions furthest re-

Read before the New York County Medical Society Academy of Medicine, April 22, 1935.
†Moschcowitz, Elli—Associate Physician, Mt. Sinai Hospital, New York City. For record and address of author see "This Week's Issue" page 632.

moved from those of hate. These mothers are not necessarily ignorant, many are well educated and some even consider themselves cultured. The state correctly demands licenses from those who are responsible for human lives, but it makes no provisions for the privilege of rearing children. One wonders whether such enlightenment will be attained in the future state. Bearing children and rearing them may some day be regarded as entirely separate callings. In recent decades due to economic pressure small families have become necessary, which probably accounts in some degree for the increase in the number of highly sensitized individuals, for it is obvious that the smaller the number of progeny, the greater the hazards of maternal domination. When a child is a single one, the chances of sensitization are almost certain. A single child starts life with almost insuperable handicaps.

Fathers are less responsible, first, because they have no nutriment-giving breasts, secondly, because they see infinitely less of their children than the mother, and thirdly, because only too often the mother is jealous of paternal influence. If a child could select the best atmosphere in which to be sensitized it would be a household with a fussy and dominating mother, a father whose interests are in everything except the rearing of children, and a horizon in which no or few rivals are visible, especially of his or her own sex.

Relatives, other than parents, have their scope for harm but only when they substitute as parents and the victim is still within the impressionable age.

There are other protective mechanisms. One of the characteristics of advancing civilization is the invention of means to soften the edges of the tools of living and the "bludgeonings of chance." Consider our subtler and swifter methods of communication, the expansion of industrialism, the enormous refinements in comfort, the vast conquest of the forces of nature.

The slow disappearance of the frontier, which Truslow Adams regards as so important in checking our economic development, has at the same time checked the pioneer spirit, the lust of adventure and aggression that was so marked a trait in the older generations.

Our own science, medicine, has also become a sensitizing influence, for the alleviation of pain, and the refinements of the sick room, while they help us to conquer, at the same time make invalidism much easier and the individual softer. Maladies that were formerly regarded by the public as minor have become major, and it pains one to say that we have developed a breed within our own calling who encourage this distorted perspective.

Certain races are more sensitive than others, but, I believe this is the result of extraneous factors and not of genetic qualities. In general,

Southern races are more sensitive than Northern, this is probably due to climate which makes the emotions of Southern people more labile. But there are other reasons that apply to isolated cases. Our Southern women are notoriously more sensitive because of the chivalrous attitude of their male associates. Primitive peoples are less sensitive than those that are civilized, and in a general way, the greater the civilization the greater the potentiality for sensitization.

This is readily understood when one considers that increasing complexity of life brings corresponding mechanisms for protection. It is a remarkable phenomenon that as soon as a primitive folk comes into prolonged contact with a civilized one, evidences of sensitization become manifest. This is well exemplified in our Negroes. Formerly Graves' syndrome was a rare disease in Negroes, at present it is common and appears to be increasing. The notorious sensitivity of the Jews is undoubtedly due to generations of persecution and the development of keen protective mechanisms, as the result of the conflicts engendered by the Diaspora. Religion may be a sensitizing agent only when it teaches irreconcilability in the face of death, if reward is promised, such as heaven or immortality, death arouses little fear. Religion may be regarded as one of the escapes from a world of reality and probably the most widespread neurosis that has affected mankind. Religion is therefore a result and not a cause of sensitivity to life.

Education is the most potent antagonist of neurosis, for fear is bred of ignorance. Scientists are not so subject to anxiety and kindred neuroses as those who lack the scientific discipline. Scientific discipline connotes the ability to doubt while the sensitive depend for their conduct in life upon dogma. It is not in the diffusion of knowledge that education fails, but rather when it teaches such protective mechanisms as the inviolability of tradition, rigidity of thought, the sanctity of conventions, and the virtues of a soft, smug, and complacent life.

Thus far, in this discussion, the influences that make for sensitivity, either of the individual or of the mass, have been entirely environmental. Sensitivity, in other words, represents a mutual reaction, a give and take between the ego and its surroundings that is progressive as life increases in complexity and intensity. I do not believe that sensitivity is congenital except under two conditions. First, when there is a congenital deficiency in the individual's physical frame or the basic intellectual potentials, so that he masks his deficiency in various forms of compensatory mechanisms. Lord Byron with his deformed foot is an example of physical inferiority that comes readily to mind. Acquired deformities, especially if they arise in the early years, may result similarly. The second is the sensitivity both to phys-

ical and mental insults that accompanies that curious morbid state known as status thymico-lymphaticus which has all the earmarks of a congenital lesion. It is well recognized that this lesion is a common background upon which Graves' syndrome is engrafted. Indeed, over 95 per cent of the fatal cases of this malady are associated with status thymicolymphaticus. The cause of the sensitivity is a mystery.

The manifestations of a heightened sensitivity to life are largely functional and range from the milder aberrations of behavior to major hysteria and even to manic depressive psychoses. I have already referred to certain maladies of organic character such as Graves' syndrome, hypertensive disease (essential) and peptic ulcer, which I believe are of psychogenic origin. Of these, Graves' syndrome is the most exquisite example. I tried to show in a previous study¹ that this syndrome expresses biologically a series of events ranging from the primitive form variously represented under the terms autonomic imbalance, Basedow, pre-Basedow, formes frustes to the complete florid stage conventionally termed exophthalmic goitre. The dominant characteristic of this malady is a constitution that is largely phenotypic. The disease occurs in highly sensitive, emotionally unstable folk and the clinical manifestations are brought to light as a general rule either by catastrophic emotional insult, or by less perceptible reiterated mental shocks. The hyperthyroidism is secondary, probably the most important clinical manifestation, and therefore should by no means be considered as synonymous with the disease. Psychotherapy is an important adjunct in the treatment of the disease not only before but even after thyroidectomy. The evidences of sensitivity in hypertensive disease (essential) and in gastric ulcer are not so apparent as in Graves' syndrome, but inasmuch as conflict enters so largely into their genesis the matter of sensitivity is entirely a relative one.

It is agreed that neuroses represent an attempt at adjustment, an escape from the world of reality and an attempt to hurdle life's difficulties. As Wechsler aptly puts it, a neurosis is the penalty for the unsuccessful attempt to grow up. Such escapes manifest themselves in a variety of disturbances of conduct: the phobias, anxiety neuroses, exaggerated narcissism, compulsion neuroses, hypochondriasis, doubting folies, psychasthenias, etc. But there is a host of other manifestations of escape that are not as a rule classed among the neuroses, these aberrations of behavior are so slight that society not only condones but even approves of them.

One of the most conspicuous symptoms of sensitivity is the overdevelopment of the instincts and the senses. This is obvious when

one considers that an escape from the realities of the environment leads naturally to a greater dependence upon one's own inner fires. And thus the instinct of self preservation becomes extraordinarily refined and enhanced; jealousy, hate, love, and fear become powerful weapons. The emotional life of those who are thus affected covers a wide range. They lack poise and phlegm, they become profoundly narcissistic, self absorbed and self pitying. Sensuality becomes their predominant characteristic. They take easily to drink and sedative drugs because they want to forget. I take it that this represents a sort of death wish. Their passions are always aflame. They indulge in sexual excess. If these are for various reasons frustrated, perversions and especially homosexuality often ensue. As a consequence their married lives become unstable. They plunge deeply into religious cults and into philosophies tinged with mysticism. They pass speedily from experience to experience and become a restless, wayward Bohemian folk. From this group come most of our artists, poets, writers, musicians, painters and actors. We need them badly, indeed, far more than most of our captains of industry for it is they who bring romance into our lives. It is the idea of romance that people associate with Southern climes. That is why Cohen Portheim says, "The North craves the South. The South satisfies feeling. The cooler regions of the earth lead to a scientific outlook on life but it leaves an emotional void. The Northern lands have many admirers but few lovers."

Hovering over the lives of the abnormally sensitive is the constant menace of self-destruction. The vast majority of suicides, especially the young, come from these people. It may seem strange that one who loves a sensuous life so intensely should seek to destroy himself but the gratification of the senses becomes so constant and so intense that living becomes a long-drawn-out pain and it requires but a push (and it is often a ludicrously trivial one) to make a decision between life and death. Security is attained at last, but in the grave.

Having made this indictment, what is the outlook and what is the remedy? The outlook is not rosy, so far as the immediate future is concerned. We cannot stay the hand of material progress nor indeed would we be willing to do so. Nor is the permanent solution of the economic problem and in consequence the stabilization of the social order an immediate prospect, so that social service seems likely to continue as a vital public and private function. The simple life, except in the sense of a change of values must, therefore, remain an enticing dream. And so if it is difficult to mould our environment the solution must come from within.

ourselves I have already hinted at the remedy in the foregoing remarks. Escapes are not always avoidable in what Powys calls "our conscious life between two incredible eternities", but if escape we must the only legitimate and reasonable one is knowledge. By knowledge, one does not necessarily mean culture, although it helps by affording a finer sense of values, but the study of man himself. Although we cannot select our mothers and other relations, at least we can teach them. We can teach them and the rest of humanity the dark menaces of overprotection. We can teach them to face realities squarely, to appreciate the drifts of civilization and to cultivate self-reliance and self-determination and thus to achieve maturity. To accomplish this they must be taught the workings of the human mind, the springs of human motives, the proper control of the instincts and senses. Spiritual values will be prized above the material. Money will be regarded in the light of a means and not an end.

The beginnings of such an education are already visible in the recent diffusion and popularization of knowledge in regard to child and adult hygiene. But it must go much farther. The responsibility of the medical profession for this knowledge and the part that it must play in it is very important. I fear we have been rather remiss in trying to maintain the traditional medieval isolation of medical lore. The practice of medicine is no longer a matter of magic or mystery, however dark its workings may be. One of the crying defects of practice of medicine today is the appalling lack of public knowledge of the principles of medicine, not only the functional but organic. There is need to recognize not merely the external conflict with disease but the disease caused by the internal conflict. Doctors must teach people how to live as well as how not to die.

VERMONT STATE MEDICAL SOCIETY

ATROPINE FEVER IN EARLY INFANCY*

BY C K JOHNSON, M D †

ALTHOUGH I am aware that there have been several papers written on this subject within recent years, I feel sure that many of you are not familiar with the fact that atropine may cause a rise of temperature, at times very high, in a few susceptible infants. This drug is now quite generally used in young infants in the treatment of pyloric spasm or for gastro-enterospasm (colic).

It is usually used in solution made with one grain of atropine in two ounces of distilled water. One drop of this solution would represent approximately 1/1000 of a grain. The usual dose is one drop in a teaspoonful of water a little before each feeding and this dose slowly increased to two or three drops at each feeding if needed to control symptoms.

White states that atropine will cure the majority of infants with functional vagogenic gastro-enterospasm and given the principal symptoms of this condition as "(a) Extreme fretfulness, aggravated by feeding, with inability to nurse because of cramps or (colic) with (b) occasional projectile vomiting, plus diarrhea or constipation, with or without visible gastric or intestinal peristalsis and (c) without the olive shaped tumor of organic pyloric stenosis."

This tendency to spasm is most frequently

found in infants under two months of age. The cause of the fever seems somewhat uncertain. Benzing believes that the fever is of central origin, the atropine circulating in the blood is a parasympathetic toxin attacking the heat regulating vegetative centers, then, owing to the paralysis of the heat inhibiting centers, heat formation is excessive.

Physiological effects of the atropine show a scarlet flush of the face and body, dilated pupils, shallow and more rapid respiration and increased pulse rate.

Howell doubted the existence of any one center, considering that there were several coordinating systems involved. Atropine diminishes glandular activity, especially of the sweat glands and the absence of perspiration may be at least in part responsible for the fever. Howell cites Zunt's case of a man without sweat glands who developed a high fever on making the slightest effort in warm weather and he further states that this is analogous to the struggling infant deprived of its ability to perspire by atropine, but by this analogy all infants given atropine should develop a fever. It is, however, estimated that less than ten per cent of them do so.

Wood¹ attributes the temperature to paralysis of the thermogenic centers in the spinal cord, and the final fall to vasomotor paralysis.

Solis-Cohen² believes that atropine fever re-

*Read before the Vermont State Medical Society at the Annual Meeting held in Burlington October 4 and 5 1934.

†Johnson, C K.—Professor of Pediatrics University of Vermont. For record and address of author see "This Week's Issue" page 632.

sults from increased heat production due to direct stimulation of the heat center

Benzing⁴ in a study of fifty infants distinguished two groups in regard to type of reaction to atropine. The first group were definitely hypersensitive to atropine. In this hypersensitive group he found infants on a concentrated diet with insufficient fluid and thinks that dehydration favors the fever. A marked increase of tolerance was noted when the dose of atropine was very slowly increased.

Dresel states that there is much experimental evidence to prove that the parasympathetic fibers inhibit heat, and that the sympathetic fibers stimulate heat production and that atropine is a parasympathetic inhibiting agent.

Alarcon⁵ stresses that individual susceptibility varies, some infants showing signs of intolerance after one drop of a 1/10,000 solution and cites another infant who by mistake received twenty drops with each feeding, without untoward effect. He states that this phenomenon may be explained as follows: it is due to the pharmacodynamic action of the minute doses of atropine which excite the vagosympathetic system, stimulating the secretory function of the glands, chiefly of the thyroid, the resultant transient hyperthyroidism, by accelerating metabolism, produces abnormal heat. The cutaneous hyperemia and suppression of sweat which accompany the fever are vagal phenomena parallel with or consequent to it, they cannot however, be considered as causes of the rise of temperature although they are contributing factors. He states further that an important factor in the production of fever is the thermolability of the tiny organism due to innate ectothermia, together with its transitory inability to control and direct its vegetative physiology by means of the skin.

McNab reports a case, that of a four year old child who died after eating belladonna berries, the temperature reaching 110 degrees F., a few hours before death.

Beehler⁶ has reported the case of a female twenty five years of age who took three grains of atropine. She developed an axillary temperature of 105 degrees F and a red rash. Atropine was found in the urine four hours after ingestion and one drop of the urine in a cat's eye dilated the pupil in five minutes.

Benzing and others report that infants with atropine fever show a neutrophilic leucocytosis.

This atropine fever is characterized by a sudden onset and may last a few days or may disappear rapidly without any aftereffects. Stopping the drug causes the temperature to disappear, only to reappear, when more atropine is given.

Marrion⁷ says that atropine may at times lead to an increase of body temperature to 102

to 104 degrees F., not accounted for by any infection. He also states that atropine fever is not necessarily a contraindication to its use, although it is usually well to diminish the dose somewhat.

Neff⁸ states that not infrequently small doses of atropine cause flushing of the skin but that this is not dangerous or injurious. Several other textbooks on pediatrics have been consulted, some of them just off the press and about fifty per cent of them do not mention fever in connection with atropine therapy.

Munns⁹ reports a case of atropine fever reaching 109 degrees F with recovery. He states that the reaction occurs only in very young infants and may occur when an ordinary dose is given. He further states that the fever is controlled by hydrotherapy and that there are no harmful aftereffects. He does not attempt to explain the phenomenon but considers the drug a safe remedy if the dose is increased with caution.

Bass¹⁰ was one of the first to describe that which he called "the hypertonic infant" and recommended the use of atropine in these cases.

Dennett¹¹ describes the hypertonic infant and strongly recommends the use of atropine. He speaks of atropine as a specific and that its use in vomiting is of diagnostic value. He also calls attention to the fact that this drug may at times cause hyperpyrexia.

It is this fact, that many textbooks do not mention the possibility of atropine causing a temperature at times very high, and the fact that atropine is now quite frequently used in the treatment of these small infants that led me to present this paper.

I have used atropine quite extensively in infant therapy for some years and during this time have occasionally seen infants that were rather sensitive to this drug. I have however not seen many who developed high fever.

I wish to cite but two cases of atropine fever at this time.

CASE 1. A H. born December 28 1933 weight nine pounds and three ounces birth normal breast with complementary feeding from the first day. On January 1 the four day old infant vomited a little and on the sixth day the vomiting had increased and was thought to be projectile in character so at 6 P.M. 1/500 grain of atropine was given by mouth this dose being repeated at 10 P.M., also at 6 A.M. and at noon the following day. I saw this infant at 6 P.M. on this day because of a rectal temperature of 103.8 degrees F. The respiration and pulse were rapid and there was a red flush over the entire body. The physical examination was otherwise negative. The atropine was stopped and fluids given, with a drop of temperature to 99.4 degrees F at 10 P.M. There was no further rise of temperature and no more vomiting of account. It has been stated that this hyperthermia caused by atropine had a beneficial effect on the vomiting in some cases, as might have been the case in this instance. However one would hardly wish to induce the high fever purposely. I feel that in many of these in

phants three or four days old that begin to vomit, the cause is often a poorly adjusted formula rather than any instability of the infants' nervous system

CASE 2 C S, born January 23, 1933, weight seven pounds and two ounces On February 18 when twenty-five days of age and a weight of six pounds and ten ounces, with some dehydration the vomiting which had been mild before became more marked and at 6 A.M. temperature was 99 degrees F rectal At 7 45 A.M. 1/1000 grain atropine was given, at 9 30 the temperature was 102 degrees F, at 10 30 A.M. 1/1000 grains atropine, and the same at noon, the temperature then 101 4 At 2 45 1/1000 grain of atropine was given and the temperature at 3 P.M. was 107 degrees F rectal I first saw this infant at 5 P.M. No more atropine was given and the rectal temperature was 100 at 10 P.M. and remained down

MISCELLANY

ANNUAL MEETING

The Annual Meeting of the Vermont State Medical Society will be held at Rutland, Vermont, October 17 and 18 The following provisional program is submitted

- 1 President's Address George G. Marshall, M.D., Rutland
- 2 Paper Augustus B. Wadsworth, M.D., Director of Division of Laboratories and Research of the State of New York, Albany, New York
Topic "Practical Limitations of Vaccine and Serum Therapy"

- 3 Paper Ward Woolner, M.D., Past President of the Ontario Medical Association, Past President of the Medical Health Officers Association, Ayr, Ontario
Topic "Rural Health Problems, the Problems Themselves and Their Control."
- 4 Paper C. F. Whitney, M.D., Professor of Physiological Chemistry and Toxicology, University of Vermont, Burlington, Vermont
Topic "Chemistry in Relation to the Practice of Medicine"
- 5 Paper N. D. Smith, M.D., Mayo Clinic, Rochester, Minn.
Topic "Obscure Abscesses a Cause of Acute Anal Pain" (Their Diagnosis and Treatment)
- 6 Paper E. J. Rogers, M.D., and L. A. Rabinowitz, M.D., Vermont Sanatorium, Pittsford, Vermont.
Topic "Chronic Cough"
- 7 Paper Henry A. Christian, M.D., Physician-in-Chief, Peter Bent Brigham Hospital, Hersey Professor of the Theory and Practice of Physic, Harvard University, Boston, Massachusetts
Topic "Types of Edema and Their Treatment."
- 8 Paper Foster Kennedy, M.D., New York City
Topic "The Biopsychic Approach to Diseases of the Mind Its Dependence on Neurology and General Medicine"
- 9 Paper O. N. Eastman, M.D., Associate Professor of Obstetrics, University of Vermont, Burlington
Topic "Hysteroptosis"
- 10 Address James S. McLester, M.D., President of the American Medical Association, Birmingham, Alabama
- 11 Vice President's Address Frank C. Phelps, M.D., Attending Physician, Porter Hospital, Middlebury, Attending Physician, Vermont State Industrial School, Vergennes, Vermont
- 12 Paper Arthur J. Bedell, M.D., Albany, New York
Topic "Ophthalmological Diagnoses"

CASE 21391

PRESENTATION OF CASE

A forty four year old Italian woolen worker entered complaining of diarrhea.

During the past three years the patient had had frequent abdominal pains across the epigastrium, occasionally extending in an irregular manner to both lower quadrants. These pains were sometimes present for about a month or more at a time and were also absent for a similar length of time. Four weeks before admission, about an hour and a half after supper he vomited. He continued to vomit that evening three or four times in all. At the same time he developed rather severe diarrhea, moving his bowels every one or two hours. The next morning the vomiting stopped but the diarrhea continued. From that time until admission he had about eight bowel movements every day. The stools were always soft and watery, but as far as the patient knew had always been free from fresh or old blood. Accompanying these symptoms he also had a feeling of abdominal distention immediately after eating. Two hours after eating he felt a "pinching stabbing" epigastric pain which was relieved by food. At times he had a "rolling sensation" and a "rumbling" running down the left side of his abdomen to just below the umbilicus and then crossing to the right lower quadrant, where it stopped. Shortly after meals he had the sensation of "something hard and big" passing down the bowel and getting stuck in the region of the right lower quadrant. His desire for food remained good but the fear of precipitating abdominal distress prevented him from satisfying this desire so that he had practically abstained from eating meat during the past four weeks. During this same period he had cramplike pains in the calves of his legs which had increased in severity. He became progressively weaker and lost about twenty pounds in weight.

The family marital and past histories are non-contributory. There was no history of tuberculosis or carcinoma. He had had pneumonia twenty years before admission.

Physical examination showed a fairly well

developed and rather poorly nourished man in no immediate distress. The mucous membranes were pale. The heart and lungs were negative. The blood pressure was 104/60. There was slight tenderness in the right lower quadrant. No masses could be felt. There were a few small external hemorrhoids. Rectal examination, however, was negative except for slight tenderness.

The temperature was 98.4°, the pulse 78. The respirations were 22.

Examination of the urine was negative. The blood showed a red cell count of 3,120,000 with a hemoglobin of 50 per cent. The white cell count was 9,700. 66 per cent polymorphonuclears. The stools were small, soft and brown. Three out of seven stool examinations showed positive guaiac tests. No amebae could be found. A Hinton test was negative.

A barium enema showed a definite delay in the passage of the barium at the rectosigmoid junction but then a small quantity of barium entered the descending colon and flowed to the region of the splenic flexure. The remainder of the colon could not be filled but a definite lesion could not be demonstrated.

On the fourth day a red non-ulcerating polypoid mass on the right wall of the region of the rectosigmoid was removed during proctoscopy. The pathologic diagnosis was adenomatous polyp. One week after admission he had considerable vomiting, abdominal cramps and diarrhea so severe as to amount to incontinence. He became severely dehydrated. The blood pressure was 70/50. He was given 4 liters of 10 per cent glucose with marked benefit. One observer at this time felt a small, hard mass in the region of the cecum. Another enema on the tenth day showed that the sigmoid was somewhat spastic but no lesion could be made out. The cecum was quite irregular but a definite diagnosis could not be made. During the examination the patient vomited several times and was unable to retain all of the enema. Two weeks after admission an exploratory laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

Dr. HENRY H. Faxon. Intermittent epigastric symptoms of three years duration would immediately suggest a gastric ulcer until proved otherwise. Radiation from the epigastrium to both lower quadrants however is distinctly atypical for any common type of pathology and raises doubt as to how much weight to lay on this part of the history.

"Four weeks before admission about an hour and a half after supper, he vomited." There is such an abrupt transition between the rather mild three year story and the severe symptoms which have been present for only four weeks that one is forced to raise the question whether this is a new lesion or some type of fairly dra

matic change in that of which he originally complained

"Two hours after eating he felt a 'pinching, stabbing' epigastric pain which was relieved by food." Relief so long after eating would be rather atypical of an ulcer and might better fit the picture of gastric malignancy.

The "rolling sensations" and rumblings spoken of are suggestive of a certain amount of obstruction with which the vomiting would also be in keeping. However, if the obstruction (which with his diarrhea would have to be incomplete in nature) were located in his upper intestinal tract it should not have radiated to his lower abdomen. If, on the other hand, as seems more likely, the site of the obstruction were in his large bowel, it is difficult to correlate the epigastric pain of which he also complained.

"Shortly after meals he had the sensation of 'something hard and big' passing down the bowel and getting stuck in the region of the right lower quadrant." Again in all probability this is gas in the face of a certain amount of obstruction.

In an Italian the possibility of some parasitic infection as a cause for the whole picture cannot be overlooked and with the muscle pain mentioned here trichiniasis comes to mind. There is no report subsequently, however, of any increase in the eosinophilic count which would be expected in most of these conditions. We find later that he had a considerable degree of anemia, so that the pain in the calves of his legs may have been on the basis of insufficient oxygenation of these muscles.

His weight loss most probably could be largely attributed to his very restricted diet, although of course, the effects of malignancy might also be a factor.

Tenderness in the right lower quadrant is often hard to evaluate since gas in the cecum is always somewhat tender to pressure, and granted the assumption that a certain amount of large bowel obstruction was present I would expect that there would be more than the average amount of gas in his ascending bowel.

His secondary anemia, it would seem to me, could best be explained in the light of the whole picture as being due to malignancy. Taken in conjunction with the normal temperature it would seem that his pathology was not primarily infectious in type.

"Three out of seven stool examinations showed positive guaiac tests." Certainly this clinical finding is of more significance than his story that blood in the stools had never been noted. However, these two factors taken together would suggest that the degree of hemorrhage at any one time had never been severe.

"No amebae could be found." If properly carried out this should rule out amebic dysentery as a cause of his symptoms.

Although no definite diagnosis was made on the first x-ray examination, this study gives more of a lead than anything we have met so far. Certainly from this report it can be definitely stated that some abnormality involving the large bowel was present.

"On the fourth day a red non-ulcerating polypoid mass on the right wall of the region of the rectosigmoid was removed during proctoscopy. The pathologic diagnosis was adenomatous polyp." Had any definite abnormality of the mucous membrane of the rectum itself been noted I assume that it would have been stated in this report. The finding of the polyp in itself is of significance chiefly due to the fact that it is well recognized that polyps are apt to be multiple, and it is more than likely that elsewhere in the large bowel additional polyps might be found any of which conceivably could have undergone malignant changes.

"One week after admission he had considerable vomiting, abdominal cramps and diarrhea so severe as to amount to incontinence." I can not stress too strongly the added help that it would be to know whether the abdominal cramps referred to were above or below the umbilicus. If the latter were the case I could discount to a considerable extent his upper intestinal symptoms, whereas if these cramps referred to were above the umbilicus some correlation between his large bowel pathology and upper intestinal tract would have to be made. Considering that vomiting is also a noteworthy symptom I am inclined to believe that the upper intestinal tract is probably involved secondarily by mechanical interference.

"He became severely dehydrated." Certainly with diarrhea of the extent this man had, dehydration would be a prominent symptom if not vigorously combated by a high fluid intake.

"The cecum was quite irregular but a definite diagnosis could not be made." This finding together with the fact that one observer believed he felt a mass raises the question as to whether the lesion might not be in the cecum or ascending colon. Malignancy could well account for the secondary anemia and it is characteristic of right-sided lesions to bleed to a considerable extent. However, with a right-sided lesion a diarrhea of the degree that he showed would, I believe, be unusual, and the obstructive symptoms also, which I cannot but feel play a part in the picture, would be more unusual with carcinoma of the cecum than with a lesion further along the large intestinal tract.

We are not told at any time what x-ray studies of the stomach and small intestines showed. Such an examination would, of course, have been of value from a threefold point of view. It would be of help in excluding any gastric pathology, it would help clear up the problem of upper intestinal obstruction, and it would give the definite lead to any spontaneous anasto-

mosis that might have occurred between a lesion of the large bowel and the stomach or upper abdominal tract.

When the above facts are evaluated the most significant definite points we have to go on are the fact that a forty four year old Italian has a bleeding lesion of his gastrointestinal tract associated with a diarrhea and with x ray findings suggestive of a lesion in the large bowel. Many of his complaints, however, are referable to the upper intestinal tract. I believe that he had malignancy of the large bowel, most probably located in the transverse or descending colon. I picture the lesion as causing a partial obstruction of the large bowel and, due to extrinsic involvement, a certain amount of associated upper intestinal obstruction as well.

CLINICAL DIAGNOSIS

Carcinoma of cecum (colloid adenocarcinoma grade III)

DR. HENRY H. FAXON'S DIAGNOSIS

Carcinoma of large bowel (probably transverse or descending colon)

ANATOMIC DIAGNOSES

(Carcinoma of cecum)

Operative wound Transverse ileocolostomy resection of cecum

Peritonitis, acute localized

Lung abscesses, bilateral

Bronchopneumonia, left

Bronchiolitis obliterans, very slight

Pleuritis, chronic fibrous, bilateral

Benign adenomatous polyp of rectum

PATHOLOGIC DISCUSSION

DR. TRAUB B. MALLOREY The preoperative diagnosis in the house was in agreement with Dr. Faxon—that there was a carcinoma of the large bowel—although they placed it in the cecum rather than in the transverse colon, evidently taking the questionable mass in the right lower quadrant fairly seriously. The patient was transferred to the surgical service where a right rectus incision was made and the peritoneal cavity explored. A rather large adherent tumor mass was found in the ascending colon which extended almost up to the hepatic flexure. The patient's condition was considered too poor to attempt radical extirpation at this time; so an ileocolic anastomosis was performed. Following this operation the patient's condition steadily improved for a two-week period. Then a second operation was performed in the attempt to resect the growth. It was found to be firmly adherent to the lateral wall of the duodenum and it proved necessary to resect a portion of the duodenal wall along with the cecum and ascending colon. The op-

erator felt that very probably a fistula between the colon and duodenum had been present although it was not possible to verify this with certainty from the resected specimen. The pathologic examination of the specimen showed a polypoid, fungating, slightly ulcerated tumor mass, from the base of which induration extended a considerable distance into the adjoining intestinal wall. The microscopic examination showed a colloid adenocarcinoma and also proved that the duodenal wall was deeply invaded.

Following this second operation the patient's course was progressively downhill. Abdominal spasm was noted for three days but then disappeared. He ran a moderate fever ranging from 100° to 101° and the respirations, after remaining at 20 for the first fifteen days, climbed to 30. Coarse râles were heard at the left base and slight dullness was made out. A portable chest plate showed mottled dullness involving the mid portion of the left lung field and the entire right lung field. It was considered characteristic of bronchopneumonia.

The autopsy showed two localized areas of peritonitis—one immediately beneath the abdominal incision, the second occupying the entire cecal bed and extending up to and around the lower pole of the right kidney. The surgical suture lines all appeared tight and in good condition and no evidence of a fistula could be made out in the remaining portion of the duodenum. It was felt that this localized peritonitis was probably not an important factor in the fatal termination. A much more important lesion was a series of lung abscesses varying from 1.5 to 6 centimeters in diameter which were filled with necrotic, blackish, foul smelling material. The abscesses were apparently still in the developmental stage and had not as yet broken down to the point where significant amounts of their content had been discharged into the bronchi. The adenomatous polyp which had been found on proctoscopy proved to be at the junction of the rectum and sigmoid. Microscopic sections through its base confirmed the previous diagnosis of a benign polyp.

Cases of this type, where a carcinoma of the large bowel is associated with one or many benign adenomatous polyps, are very frequent and present strong presumptive evidence for the development of malignancy from benign polyps. A less common lesion, of which I thought when I read over this history, is the extreme grade of multiple polyposis in which almost every inch of the bowel wall is covered with the polypoid masses. Such cases not infrequently give a history of prolonged intractable diarrhea which may be indistinguishable from the stories of cases of ulcerative colitis.

Dr. Faxon's attempt to correlate the epigastric with the lower abdominal symptoms by the

assumption of a tumor in the transverse colon which had invaded the stomach or small bowel, with or without the establishment of a fistula, was an ingenious solution of the perplexing symptomatology, and the actual finding of a carcinoma of the ascending colon involving the duodenum is so close that he deserves considerable credit for having made it

CASE 21392

PRESENTATION OF CASE

A forty-one year old single American teacher entered complaining of fever of two weeks' duration

Three months before entry the patient had an attack of "ptomaine poisoning," apparently due to lobster, which kept her in bed for two weeks. She was acutely ill during the first week with abdominal pain and fever. After this she was perfectly well until two weeks before entry when she developed a sore throat and "ached all over." She went to bed and stayed there until admission with a temperature of 101° to 102° every afternoon. After about a week the sore throat subsided somewhat, although it was red and covered with membrane. The cervical glands were enlarged. During the first week she sweat a great deal but had no chills. There was no cough or pain in the chest. She had herpes of the lips and nose. During this illness she had been given digitalis. There was no vomiting, diarrhea or abdominal pain. She had no urinary difficulties. Her menstrual history was negative.

Her family history is non-contributory.

She had an unknown fever at the age of five, scarlet fever at twelve, diphtheria at twenty-three and repeated attacks of tonsillitis. At the age of eighteen her appendix was removed. Seven years ago she was said to have a heart murmur. During the past three years she had slight dyspnea and palpitation upon exertion. She was seen by a cardiologist two years before entry and a diagnosis of mitral stenosis was made. She was not reexamined until four months before entry and the heart condition had not essentially changed.

Physical examination showed a pale thin, sick-looking woman lying in bed breathing a little rapidly. Her throat and tonsils were moderately infected and dull red but contained no exudate or membrane. The heart was enlarged, the left border of dullness being 11.5 centimeters from the midsternal line, the right 3 centimeters. There was a systolic wave over the precordium and a short presystolic thrill at the apex. The sounds were loud. P_2 was slightly louder than A_2 . There was a middiastolic rumble heard best toward the axillary line. The chest showed some dullness with bronchial breathing, decreased breath sounds and a moderate number of moist râles at the left base.

The liver was felt 12 centimeters below the costal margin in the midclavicular line and was non-tender. There was no evidence of fluid in the abdomen. The spleen was not felt. There was no edema of the ankles. No petechiae were seen. The knee jerks were not obtained.

The temperature was 102.1° , the pulse 110. The respirations were 38.

Examination of the urine showed a specific gravity of 1.028 with a trace of albumin. The sediment contained 30 white blood cells, 15 red blood cells and numerous bacteria. The blood showed a red cell count of 4,060,000, with a hemoglobin of 70 per cent. The white cell count was 24,000, 87 per cent polymorphonuclears. The stools were negative. An electrocardiogram showed normal rhythm, rate 80, broad notched P_1 and P_2 and right axis deviation. The P-R interval was 0.18 seconds.

Examination on the third day showed no real changes except those in the lungs. The right chest was quite dull and the râles persisted. The previous bronchial breathing had subsided. In the left axilla, however, there was an area of dullness with a suggestion of bronchial breathing and râles. No friction rub was heard. There was very little cough and no sputum. She rapidly went downhill. The temperature, which at first went down to between 100° and 101° , rose on the fourth day to 103.5° . The white cell count rose to 33,200. The edema increased. She became progressively weaker, moderately cyanotic and died on the fourth day.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM B BREED. I do not like to call this intestinal episode ptomaine poisoning if it was simple food poisoning. She was well after two weeks. Well, either it was food poisoning and had nothing to do with the present illness or it was not food poisoning, from lobster at least, and it did have something to do with it. I cannot tell which it was. She was well for two months and I am tempted at the moment to exclude this episode from the present illness, although it may become significant later. We will say that the present illness began two weeks before entry when she developed the sore throat and ached all over. The throat was red and covered with membrane. I should like to know a little more about the membrane, whether it was an exudate which resembled a membrane or a true membrane. I should like to know why she was given digitalis. We may find out later. She had an acute sore throat with cervical adenitis and herpes. We do not know about a culture or what the white count was, and we do not know whether she had taken any other drugs for her sore throat, such as amidopyridin, so we think either of acute streptococcus infection or possibly agranulocytosis. It may be one of the leukemias.

There is probably no diptheria in spite of the mention of the membrane.

With this story of repeated tonsillitis and the evidence she has of rheumatic heart disease, this is a perfectly good story for acute rheumatic fever. I am not clear about the association of herpes with rheumatic fever. I have never seen it. It may be associated with it or it may be incidental. I still do not bring in the food poisoning. The observation that P_2 is greater than A_2 does not mean anything unless there is an added note that P_2 is accentuated. We know that she has a sore throat and presumably tonsillitis, and there may be a flare up of rheumatic infection associated with the sore throat. Of course, the fact that she was "aching all over" in the first part of the history means that she was toxic. There is no evidence pointing to joint involvement. However, we know that that is not necessary for a flare-up of a rheumatic nature. The respirations are high. On physical examination there is dullness with bronchial breathing decreased breath sounds, and a moderate number of rales at the left base, so that she may have some process in the chest either bronchopneumonia or possibly something of an embolic nature.

The P R interval would indicate in general that she was not suffering at the time from recurrence of a rheumatic infection, and although that is not an absolute criterion it is a good piece of evidence. The summary does not say anything about a throat culture. She certainly does not have agranulocytosis or leukemia. Was a culture taken?

DR. TRACY B. MALLORY. It is not recorded.

DR. BREED. Presumably this is a streptococcus throat infection, although we do not know. We do not know about a blood culture. I presume that they were taken. She certainly had an overwhelming infection because she died of it. I think that is clear, and I should doubt that she died of rheumatic infection. She had some bronchopneumonia, probably bilateral but it does not seem reasonable to expect that she would die as suddenly as that from bronchopneumonia, as mild as it appeared to be. I do not know whether we are at a deadlock here because we have no information or because we are so stupid we cannot make a diagnosis, but the evidence that we have points merely to an overwhelming upper respiratory infection.

A PHYSICIAN. How about subacute bacterial endocarditis?

DR. BREED. The course is too rapid even for malignant endocarditis.

A PHYSICIAN. She may have had symptoms for some time before she came in.

DR. BREED. But she was well for two months.

A PHYSICIAN. How about metastatic abscess, then?

DR. BREED. I should not expect it to be found.

A PHYSICIAN. I think her death might be caused by pneumonia but there is a possibility of acute or subacute endocarditis.

DR. BREED. That is merely a guess. All we can do is guess.

I cannot make a definite diagnosis other than chronic rheumatic heart disease with mitral involvement. She died of infection. I do not know what infection other than just plain tonsillitis and bronchopneumonia. She may have had septicemia. I am sorry that the blood culture was not forthcoming.

CLINICAL DIAGNOSES

Acute rheumatic fever
Pneumonia (rheumatic)?
Rheumatic heart disease with mitral stenosis.
Uremia?

DR. WILLIAM B. BREED'S DIAGNOSES

Chronic rheumatic heart disease with mitral involvement
Acute infection—unknown etiology

ANATOMIC DIAGNOSES

(Acute rheumatic fever?)
Endocarditis, chronic rheumatic, mitral with stenosis, aortic.
Cardiac hypertrophy, rheumatic slight
Pulmonary thrombosis
Pulmonary infarcts bilateral
Pulmonary congestion and edema
Hydrothorax, bilateral
Ascites.
Petechial hemorrhage of peritoneum, pleura and pericardium
Pleuritis, chronic
Cyst of right ovary
Operative scar. Appendectomy

PATHOLOGIC DISCUSSION

DR. MALLORY. I was not too sure of the cause of death after the autopsy was over. She had a very definite, fairly severe old mitral stenosis. We could not find any fresh vegetations on the valve. There were, however, two or three minute vegetations, perfectly consistent with acute rheumatic vegetations, on the aortic valve which otherwise showed only very slight thickening. We did not find any sign of Aschoff bodies in the heart muscle. That means almost nothing, because we do not run through more than two or three blocks of heart muscle per autopsy and if you want to find Aschoff nodules you have to run fifty blocks to be certain of getting them. They can only be found with very high incidence provided you make the search for them almost a research job in each case.

The pulmonary complications were peculiar

A lot of interest has developed in the last two or three years in the question of so-called rheumatic pneumonia and any time a rheumatic case dies with anything in the lungs everybody wants to know whether it is rheumatic pneumonia. I find it very difficult to get any idea what rheumatic pneumonia is. There are many clinical reports in the literature and a few of them have some appended pathologic notes written almost invariably, I should say, by a clinician who has attempted to interpret the microscopic sections. I cannot make head or tail of the descriptions. There is one paper*, based on only two cases, however, that is fairly good from the pathologist's point of view. In most cases there are multiple areas of hemorrhage throughout the lung, rather sharply focal, looking very much like infarcts, but usually not leading to complete necrosis of the lung tissue. You can also find, microscopically, lesions in some of the very small pulmonary arteries in the immediate neighborhood of the hemorrhagic foci. Histologically the lesions are about half way between infarct and pneumonia in appearance. We have seen two cases here in children with acute rheumatic fever that correspond to that picture. We have seen a lot of atypical pneumonias of other kinds in other rheumatics, and so far I have no clear conception as to whether there is a rheumatic pneumonia entity. This woman had a large number of fairly small but definite infarcts scattered throughout the lung. There was no doubt of their being real infarcts. The alveolar walls were becoming necrotic and we could find thrombi or proba-

bly adherent emboli in the arteries leading to each of the infarcts. We did not find any thrombi in the right side of the heart, so it is unlikely that they came from there. I imagine that she was getting emboli from some uncovered phlebitis of the leg. One always thinks of pulmonary infarcts as a surgical or rather post-surgical disease. As a matter of fact pulmonary infarcts are fairly common on the medical wards but are almost impossible to diagnose except in very characteristic cases where you have a localized pleuritis and frankly bloody sputum or a lead in the form of an obvious phlebitis. One certainly can have thrombosis in the deep veins of the leg which is absolutely silent. The postmortem blood culture was negative. There is no proof, therefore, what the fever was but on the whole rheumatic fever seems as good a bet as any, mostly because of the indefiniteness of the findings.

DR. BREED It is unusual for a person of her age to die as quickly as this of rheumatic fever, although children die of rheumatic fever oftener than is generally supposed.

A PHYSICIAN How about the liver?

DR. MALLORY It was normal in size. It weighed 1600 grams which is within normal limits. The spleen weighed 225 grams. She simply had a low diaphragm.

DR. BREED We all agree that she probably had an old mitral stenosis and that she died of acute infection, with a question of rheumatic fever. I guess that is the best we could say.

TUBERCULOSIS—AN ANOMALY

TUBERCULOSIS holds a unique place among the communicable diseases—unique, that is, in the attitude of the public, of physicians and of public health officials. With other infectious diseases, the first evidence of their presence starts the operation of a series of events carefully planned to prevent their spread. The first act, after initiating treatment of the patient and reporting the disease, is to search for the source of the infection. While this quest is going on, precautions are taken to prevent the patient from passing on the virus to others. The sick one is surrounded by safeguards, those nursing the sick are instructed in ways for shielding themselves and others against the infection, the room or the house may be quarantined or the patient removed to an isolation hospital. In our archaic handling of that disease of low transmissibility, leprosy, we even banish the leper to exile. If the source of the disease is found to be a harbinger of diphtheria

bacilli, we sequester the carrier until cultures show the disappearance of the bacilli, and, sometimes, when they remain persistently positive, we, if permitted, remove the tonsils. The typhoid carrier is excluded from all occupations connected with food handling, and when we are successful in our persuasion, we take out the gall bladder.

The yellow flag, the quarantine card, the gossip of neighbors warn that danger is present. But, with tuberculosis, the order is changed. The source, the open case, spreading living tubercle bacilli, is sympathized with, precautionary instructions may or may not be given, and the attending physician, when there is one, is frequently casual in the announcement of his diagnosis. And, as our city and state vital statistics show, he may report the case to the local health authorities sometimes as late as a month or a week before death, and all too often after the demise of the patient.

Our city, county, state and veterans' hospitals are intended for the removal of the infectious patient from his or her surroundings, but frequently the waiting lists leave the open case at home. But many of these institutions prefer the favorable case. For chronic phthisis sufferers there are hospitals especially planned for their care, but there are too few of them and it is often impossible to persuade such a patient to leave his home and family circle and to enter an institution known as a resort for incurables. So the source of this disease may be allowed to go about his occupation as long as he is able and then to rest and die, likely, to spread infection in the midst of his susceptible relations and friends.

Tuberculosis, we realize, does not present the immediate and frightening menace of diphtheria, scarlet fever or smallpox, but it causes a greater economic loss, a heavier drain on the efforts and funds of our charitable organizations and a greater sacrifice of human lives.

The voluntary, philanthropic societies have been wholly admirable in their efforts to control this disease. Their education of the public in the ways of good living, of the predisposing causes and early symptoms of tuberculosis, their preventoria and sanatoria for the threatened or afflicted, their vocational training for the convalescent deserve the highest praise for their nobility of purpose and their splendid achievement. Their aims are both preventive and palliative, but many an active case escapes their search and having no official authority they can only control these human sources of infection by suasion.

If we examine their programs or those of health departments, we are impressed by their emphasis on the strengthening of health, on early diagnosis, and on the medical and surgical care of the tuberculous. If we read the jour-

nals devoted to this disease, we learn about the biology of the tubercle bacillus, about epidemiological features, new diagnostic aids, the use of this or that remedial agent, the management of hospitals and sanatoria, but in all these publications we find so little about the reporting and control of the open case

In our private and public campaigns we are now experiencing the operation of the law of diminishing returns. The declining curves of morbidity and mortality from tuberculosis are flattening, and it requires still greater effort to reduce the rate by a point

Every case of tuberculosis comes from another case, either in a cow or man. Our official federal and state agriculturists are persistent in their determination to rid the country of infected cattle, but we, perhaps because of the difficulties presented by sentimentalism, must be more gentle in the disposition of our human wells of infection. For the control of other communicable diseases our laws are largely mandatory, for the control of tuberculosis they are mostly permissive

So many of the baffling problems presented by other plagues have been solved, that we are confident of ultimate success in controlling this particular disease. More intensive search and closer control of the open case would speed us along the way. It is, after all, the tubercle bacillus that causes tuberculosis, and it is the purpose of this editorial to focus closer attention upon this neglected, difficult and eminently important feature of tuberculosis eradication in man

A PHYSICIAN'S HANDBOOK

THE actual practice of medicine proves to be so much greater than and so different from those aspects of practice to which the attention of medical students was formerly directed in order that they might gain a knowledge of disease, that the study of so-called disease entities has been supplemented by more or less complete study of the conditions in which disease arises and develops and must be treated. The supplementary aspects of disease may be characterized as involving environmental factors, among which are the social elements. There is involved, then, first the study of the individual who is sick, and then the study of the society of which he is a part, in which he is sick, on which he acts and which reacts to him

Several years ago there was published under the auspices of the Massachusetts General Hospital a "Physician's Handbook of Community Resources in Metropolitan Boston, together with Certain Legal Responsibilities", which was made possible by the benefaction of an anonymous donor. The idea of such a handbook seemed excellent, the booklet has filled a long-felt need and the results have justified the un-

dertaking. Has the time not come for a greater development into a larger field of usefulness?

While the legal responsibilities of the physician change little throughout the Commonwealth, the Community Resources vary greatly in the different communities. A physician entering upon practice in a town or city often has little knowledge of the resources of the community and as such a physician is generally beginning practice, he may have had no experience with community resources anywhere. He knows little, therefore, of what his community can and does offer.

Medical students who have been fortunate enough to have intimate contact with the well organized medical social service of a hospital, may have some conception of what to look for and of how to go about finding what the patient needs, but too often it is only after a blundering and time-consuming experience that the physician learns what his community actually supplies.

The Massachusetts Medical Society, on admitting a physician to membership, gives him a copy of its Constitution and By-Laws. It would not be impracticable and it might be most helpful if each district of the Society provided for its members a handbook similar to that which has proved so useful in the metropolitan area. In addition it would be a step in the right direction if the Board of Registration provided each registrant, at the time of licensure, with a copy of the medical practice act and of other statutes of the Commonwealth pertaining to the practice of medicine. Dealing with the violation of these statutes is part of the duty of the Board of Registration in Medicine and it is not asking too much of the Commonwealth that it provide each registrant with a copy of the law under which he is to practice.

In any case, the issuing by the Society to its new members of a Handbook would be an extension of its educational program into a field hitherto neglected, and an additional recognition of its educational obligation toward all its members.

AN UNFAIR BURDEN

AN analysis of the burden falling on doctors and hospitals is set forth by M. J. O'Malley in the *New York Times* of August 11, 1935. He affirms that several years ago the unpaid hospital bills due to highway accidents had amounted to over \$6,000,000. "Hospital Management" in October 1931 estimated that the losses to hospitals in this country incurred in caring for automobile accidents was \$5,000,000 a year.

The Research Division of the New Jersey Department of Institutions and Agencies conducted an investigation of highway accidents which dis-

closed that in 1930 the number of persons requiring bed service in hospitals was in excess of 13,000. Nineteen general hospitals were studied as the basis of this estimate. They treated 1781 highway accident patients, who spent a total of 22,441 days in the hospitals. The bills rendered for these cases totaled more than \$100,000, but only 56 per cent of this sum was collected.

In 1930 the Ohio Hospital Association found that, of more than \$810,000 hospital charges for automobile accident patients, about 50 per cent was considered uncollectible.

During 1931-1933 inclusive, accidents within the metropolitan area of Richmond, Va. brought 4056 patients to the Medical College of Virginia Hospital and over 7000 were given out-patient treatment. The total cost to the community for the three years was \$217,000. In Philadelphia a committee found that charges amounting to \$16,410 for patients hospitalized by reason of highway accidents were made with one third unpaid at the close of the year following the accidents. In all cases, fatal and otherwise, studied by this committee, one bill in sixteen was paid.

In England it is provided that the driver of a car involved in an accident causing personal injury must pay for emergency treatment for each patient. Some of our States have tried to have laws enacted which will protect doctors and hospitals in caring for victims of automobile accidents. Senator Miles tried to have the law passed in Massachusetts with this object in view. Lawyers claimed that the bill as drafted was unconstitutional. It is strange that a great injustice cannot be remedied. No one, so far as reports are available, has computed the unpaid bills for doctors' services for these accident cases.

If this burden on hospitals and doctors can not be remedied by existing or proposed laws there should be a further study of the subject. It is reasonable to expect that the public will endorse an appropriate remedy.

POSTGRADUATE TRAINING IN MEDICINE

A DISPATCH to the *New York Herald Tribune* of August 15, 1935, quoting from the *German Doctors' Journal* sets forth that the "Aryan" physician of the Third Reich must take a compulsory training course of three weeks once every five years. The evident purpose of this requirement is to elevate the standards of medical practice in Germany.

General practitioners of cities and towns of less than 100,000 residents will be called first to take the prescribed courses with certain exceptions.

This plan apparently recognizes the general

belief that doctors as a class do not keep in step with medical progress.

This state of affairs is not confined to Germany and its recognition in the United States is shown by the facilities for postgraduate study which are available for every doctor who is desirous of keeping up to date. The trouble with us is that those who need instruction and training most, are least apt to avail themselves of the opportunities provided by societies and medical schools, with the result that there is a substratum of unprogressive doctors. It has been said that only about forty per cent of our doctors attend medical meetings conducted by District Societies and there are many who do not read medical journals.

Nothing but compulsion will drive such men to study.

If the state confers the right to practice, why should the indifferent doctor be left to practice out-of-date medicine? Just because he has passed the examinations of the State Board, there is no guarantee of his progress in medical education in subsequent years. The government does not let its military surgeons retrograde or even remain static, but requires evidence of improvement at regular intervals. The custom of certification of the doctor's qualifications by one examination is hardly an adequate assurance of his capacity in the competitive field of medical practice.

The German plan is highly commendable, but would meet obstruction in America, in all probability. Our people want freedom from supervision even in the practice of medicine.

A SUIT AT LAW AGAINST AN OFFICER OF THE MASSACHUSETTS MEDICAL SOCIETY

DR. DAVID CHEEVER, Chairman of the Committee on Ethics and Discipline of the Massachusetts Medical Society, has been sued by Dr. Nicandro F. DeCesare for libel. The claimant places fifty thousand dollars as the financial damage. Dr. DeCesare resides at Methuen and has an office at 57 Jackson Street, Lawrence.

This action of Dr. DeCesare is based on statements made by Dr. Cheever in the performance of his duty as defined in the By Laws of the Society in the investigation of certain charges concerning Dr. DeCesare made to the committee of which Dr. Cheever is Chairman. It became Dr. Cheever's further duty to present the facts bearing on the charges which had come to the attention of his Committee to a Board of Trial appointed by the then President, Dr. W. H. Robey.

It is also of interest to Fellows of the Massachusetts Medical Society that Dr. Daniel Fiske Jones, who originally brought the matter in issue to the attention of the Committee on Ethics and

Discipline, has also been sued by Dr DeCesare for fifty thousand dollars

After hearing the evidence, the Board of Trial unanimously reported to the then Secretary of the Massachusetts Medical Society, Dr W L Builage, its opinion that Dr DeCesare was guilty of the acts defined in the complaint but after deliberation appended to the report differences of opinion as to the appropriate disciplinary measures to be adopted by the Society

This report of the Board of Trial was submitted to the Annual Meeting of the Society June, 1935 The Society then referred the material which had been submitted to the Board of Trial to a large committee representing all sections of the Society for a review of the proceedings and a report to be submitted at the next annual meeting of the Society

It is felt that the Fellows of the Society are entitled to this general statement of this case, but the *Journal* refrains from the publication of details and explanations until the Society shall have taken final action

The reference of this controversy to the courts also requires a conservative attitude by this *Journal*

THIS WEEK'S ISSUE

STATED MEETING OF THE COUNCIL

A STATED meeting of the Council of the Massachusetts Medical Society will be held in John Ware Hall, Boston Medical Library 8 Fenway, Boston, on Wednesday, October 2, 1935 at 12 o'clock, noon

Business

- 1 Call to order at 12, noon
- 2 Reading record of last meeting in abstract
- 3 Report of Committee of Arrangements for Annual Meeting
- 4 Report of Committee on Membership and Finance
- 5 Reports of committees to consider petitions for restoration to the privileges of fellowship and appointment of new committees.
- 6 Appointment of an auditing committee
- 7 Fill any vacancies in the offices of the Society
- 8 *Incidental Business*

ALEXANDER S BEGG *Secretary*

Boston, September 25, 1935

Councillors are asked to sign one of the two attendance books before the meeting

TRICHOMONAS VAGINALIS

Trichomonas vaginalis is a fairly common condition responsible for many cases of annoying leukorrhea. To make the diagnosis it is necessary only to place a cotton swab on an applicator, rub it firmly over the vaginal walls and wash it off in a few cc. of warm normal saline solution. From this a hanging drop can be made, or a few drops may be placed under a cover slip on a slide. Examined under the high dry lens of the microscope the characteristic protozoa is readily identifiable, having moving flagella at one pole and several cilia at the other. It is pyriform or spindle shaped, larger than a pus cell but smaller than an epithelial cell.

In the presence of an acute vaginitis from this parasite the smear usually shows, in addition

A series of short selected articles by members of the Section will be published weekly.

Comments and questions by subscribers are solicited and will be discussed by members of the Section.

tion to the trichomonads, large numbers of pus cells, but as the condition is improved by treatment the pus cells diminish rapidly in number leaving the usual preponderance of normal epithelial cells. The discharge produced is often very profuse, yellowish white, thin or mucoid, sometimes foamy, with a foul odor, it appears on a vaginal wall which is inflamed and frequently covered with fine petechiae. In addition to the discharge the patient usually complains of an itching or burning sensation at the introitus and of dyspareunia. Dysuria is often present, frequency is not so common.

It is trite to remark that the almost countless forms of treatment which have been recommended only suggest the many failures of each. Space does not permit even a résumé of the various measures which have been advocated. The writer has been so well satisfied, however with a method which was suggested to him by Dr Mortimer Hyams of New York that he has had no extensive experience with any other, and will here limit his discussion to this treatment.

The vagina is scrubbed with cotton saturated in half strength tincture of green soap and left for five minutes. The soap is next thoroughly washed out with an irrigation of hot mercury oxycyanide solution 1:3000. A speculum is introduced the vaginal walls dried with cotton gauze, and two drams of one per cent picric acid in glycerine poured in. The vagina is then packed with a gauze pad and the patient is directed to remove the packing twenty four hours later. For the first two or three weeks the treatments should be given every second day, but after that they may be spaced farther and farther apart. In addition to these treatments the patient is advised to take a slow two quart douche of hot 1:3000 mercury oxycyanide solution each night before retiring except on those days when she has been treated. The douches are continued through the menstrual periods.

The patient should not be considered cured until she has been found free of any trichomonads when examined directly after the menstrual period for several consecutive months. And because recurrences are not uncommon it is safer to advise reexamination at the end of another six months. It must be borne in mind, however, that there is at least a theoretical possibility of mercury poisoning if the douches are continued indefinitely, and for this reason their use should be limited to a few months at a time.

A high percentage of cures is certain with almost any of the recognized treatments if the patient is cooperative and the physician persistent in his efforts. And the woman who has had to wear perineal pads constantly or douche daily for months or years because of this foul discharge is most appreciative of the result.

MISCELLANY

THE SUCCESSOR TO DR MAGRATH

With the announcement of the resignation of Dr George Burgess Magrath from the position of medical examiner of Suffolk County because of ill health, His Excellency, Governor Curley, plans to advance Dr William J Brickley, associate examiner, to fill this position when Dr Magrath vacates the office. The acceptance of Dr Magrath's resignation will be deferred in order to allow him to qualify for a pension under the county retirement system. This is in recognition of the long and valuable service rendered by Dr Magrath.

With the advancement of Dr Brickley, the Governor plans to appoint Dr Cornelius J O'Leary to the position of Associate Medical Examiner, according to reports in the daily press.

Dr Brickley has enjoyed the confidence and respect of the citizens of Suffolk County for the energy and ability displayed in his attention to the duties of the office of Associate Medical Examiner. By education and experience he is well fitted for the higher position.

Dr O'Leary was born in 1902, graduated in medicine from the Tufts College Medical School in 1933 and served as interne at St. Elizabeth's Hospital. He is a member of the staffs of St. Elizabeth's, the Cambridge and Waltham Hospitals. He is bacteriologist for the Boston Department of Health and a Fellow of the Massachusetts Medical Society.

CONNECTICUT CITIES ARE STUDYING
NON-PROFIT HOSPITAL SERVICE

In an address before the Clinical Congress of the Connecticut State Medical Society, September 18, Mr Van Dyk, executive director of the Associated Hospital Service of New York, reported that plans are being considered for non-profit hospital service in New Haven, Hartford, New Britain, Norwich, Derby, Norwalk, Bridgeport, Torrington, Meriden and Danbury.

TUFTS COLLEGE MEDICAL SCHOOL
'NEWS ITEMS

Dr Siegfried J Thannhauser, formerly Medical Director of the University of Freiburg, has been appointed Associate Professor of Medicine.

Four scholarships of the value of \$1,000 each, known as the Commonwealth Fund Scholarships, are awarded annually to properly qualified medical students. The recipients of these scholarships must agree to practice medicine in a rural community for a period of three years. The scholarships are awarded with the understanding that they will be renewed for each of the years required for graduation in medicine, provided that the record of the recipient warrants such extensions. Applicants must be residents of Massachusetts. The following selections have been made for the coming year:

- Walter F Crosby, Danvers, Mass., Bowdoin, '35
- Bronislaus A. Galuszka, Chicopee Falls, Mass., Tufts, '35
- Marshall A. Lamb, Rockland, Mass., Harvard, '34

Horatio J Young Florence Mass., Johns Hopkins, '35

It is anticipated that the tuition of the medical school will be increased to \$500.00 a year and the enrollment limited to 100 beginning with the fall of 1936

FROM NAVAL CUSTOMS TRADITIONS AND USAGE BY LT COMMANDER LELAND P LOVETT U S NAVY

UNITED STATES NAVAL INSTITUTE, ANNAPOLIS
MARYLAND 1934 PAGES 232-233

Guns, Son of a In the early days sailors were permitted to keep their wives on board. The term was actually used to refer to children born along side the guns of the broadsides. In fact, the expression questioned the legitimacy of anyone. The old definition of a man-o-war's man was,

"Begotten in the galley and born under a gun Every hair a rope yarn every tooth a marine spike every finger a fish hook end in his blood right good Stockholm tar

A British officer commanding a brig off the Spanish coast in 1835 wrote in his diary

"This day the surgeon informed me that a woman on board had been laboring in child for twelve hours, and if I could see my way to permit the firing of a broadside to leeward, nature would be assisted by the shock. I complied with the request and she was delivered of a fine male child."

The Gunnery Department surely made a perfect score—Submitted by Dr John P Monks

THE APPOINTMENT OF DR. JOHN A. HUFFMIRE

Dr John A. Huffmire of Huntington, Massachusetts has been appointed Associate Medical Examiner of the second Hampshire District and has taken the oath of office

Dr Huffmire is a graduate of the Middlesex College of Medicine and Surgery Class of 1934

THE APPOINTMENTS OF DR. JOHN V GALLAGHER AND DR. IRVING F ARMSTRONG

Governor Curley has appointed Dr John V Gallagher of Milford medical examiner of the sixth Worcester District, to succeed the late Dr George Curley and Dr Irving F Armstrong of Hudson, medical examiner of the ninth Middlesex District, to succeed Dr Norman M. Hunter

MORTALITY RATES

Telegraphic returns from 86 cities with a total population of thirty-seven millions for the week ending September 7 indicate a mortality rate of 94 as against a rate of 101 for the corresponding week of last year. The highest rate (17.3) appears for Nashville Tenn., and the lowest (8.4) for Somerville Mass. The highest infant mortality rate (185) appears for Cincinnati Ohio and the lowest for Bridgeport, Conn., Canton, Ohio Duluth Minn.

Evansville Ind., Jersey City N J., Long Beach Calif., New Bedford, Mass., Schenectady N Y., Seattle Wash., Somerville Mass., South Bend, Ind., Spokane Wash., Springfield, Mass., Tacoma Wash., Utica, N Y., and Yonkers N Y., which report no infant mortality

The annual rate for 86 cities is 11.6 for the thirty six weeks of 1935 as against a rate of 11.5 for the corresponding period of the previous year—Bureau of the Census

RESUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR AUGUST 1935

Disease	Aug., 1935	Aug., 1934	5 Yr Average*
Anterior Poliomyelitis	483	16	148
Chickenpox	97	87	108
Diphtheria	23	51	109
Dog Bite	1117	1031	721
Epidemic Cerebrospinal Meningitis	4	2	6
German Measles	89	15	25
Gonorrhea	546	680	661
Lobar Pneumonia	123	90	83
Measles	130	95	139
Mumps	225	131	148
Scarlet Fever	175	179	249
Syphilis	444	401	351
Tuberculosis Pulmonary	824	840	321
Tuberculosis Other Forms	35	40	37
Typhoid Fever	15	24	34
Undulant Fever	2	0	
Whooping Cough	293	596	568

Based on the figures for the preceding 5 years.

RARE DISEASES

Anterior poliomyelitis—483 cases (see weekly lists)

Anthrax was reported from Sheffield, 1.

Dysentery (bacillary) was reported from Somerville 1 Watertown 1 total 2

Encephalitis lethargica was reported from New Bedford 1 Swampscott, 1 total 2

Epidemic cerebrospinal meningitis was reported from Belchertown 1 Cambridge, 1 Medford 1 Norwood 1 total 4

Malaria was reported from Watertown 1

Pellagra was reported from Boston 1 Watertown, 1 total, 2

Septic sore throat was reported from Athol 1 Boston 3 Brookline 1 Lynn 1 Winthrop 1 total 7

Tetanus was reported from Fall River 1 Hingham 1 Watertown 1 total, 3.

Trachoma was reported from Boston, 2 Worcester 1 total, 3

Trichinosis was reported from Boston 1 Methuen, 1 total 2.

Typhus fever was reported from Beverly 1

Undulant fever was reported from Cambridge, 1, Greenfield, 1, total, 2

Infantile paralysis was at its highest reported August incidence with foci in Boston and Fall River and a scattering of cases throughout the eastern part of the state

Diphtheria was at its lowest reported monthly incidence in the history of the state

Lobar pneumonia continues to show an increase over last year's figures, which may mean an increased prevalence throughout the coming winter

German measles had the usual summer decline after a year of epidemic incidence, with a possibility of another year of increased prevalence in 1936

Typhoid fever, with a total of 76 reported cases to date, shows no increase over the 1934 record low figure

Tuberculosis, pulmonary and other forms were reported to about the usual expectancy

Epidemic cerebrospinal meningitis, measles, mumps, and chickenpox showed nothing remarkable

Scarlet fever and whooping cough are running lower than in 1934

THE CAMPAIGN TO DIMINISH AUTOMOBILE ACCIDENTS

The Boston Traveler is engaged in a campaign to reduce the number of automobile accidents and in order to secure the influential cooperation of doctors has deposited at the Boston Medical Library copies of the Safe Driving Pledge with the request that doctors be asked to sign and forward them

This is a worthy movement and doctors may well participate in giving assurance of cooperation by signing the pledges under seven headings as follows

- 1 To drive at moderate speed and on own side of road
- 2 Not to pass cars on curves or hills
- 3 To stop at stop signs
- 4 Not to jump traffic lights
- 5 In city traffic, to be particularly watchful for pedestrians stepping into the line of traffic from parked cars
- 6 Always to give hand signals showing my intention of turning to the left, to the right, or stopping, and not to leave the curb from a parked position without giving a signal
- 7 To be fair to other drivers in all respects and to refrain from reckless driving

CORRESPONDENCE

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

September 18, 1935

Editor, *New England Journal of Medicine*,

I am writing you the following report to establish what I think is originality of action for the Middlesex South District Medical Society

Recently a meeting of the Councilors of the Middlesex South District Medical Society was called by its President, Dr Sumner H Remick. The meeting was held at the Middlesex County Sanatorium. Thirty four out of a total of fifty-one Councilors representing this District were present.

Many problems pertinent to the practice of medicine were discussed. Such problems as "the abuse of charity hospitals," "medical legislation," "post graduate study," "relief for indigent physicians" and "program" were discussed and certain plans of procedure were evolved.

Dr Charles E Mongan, the President of the Massachusetts Medical Society, was present. He acquainted the Councilors with the medical economic situation and spoke about the future activity of the Society along these lines.

The meeting of the Council of the Middlesex South District Medical Society will no doubt, in the future, become an important part of the activity of this Society and will therefore place the Councilors in a better position to assume their responsibility toward the Massachusetts Medical Society.

Very truly yours,

ALEXANDER A LEVI, M D, *Secretary*

RECENT DEATHS

MINDLIN—CARL MINDLIN, M D, of 105 Emerson Street, Haverhill, died August 20, 1935. He was born in Russia in 1884 and early in life went to New York City where his early education was acquired. He graduated from the Long Island College of Medicine in 1910 and served as intern at the Long Island Hospital. He first settled in Manchester, New Hampshire, and soon afterward moved to Haverhill where he maintained an active practice for twenty five years. He was a Fellow of the Massachusetts Medical Society and the American Medical Association. He is survived by his widow, Mrs Ada Mindlin, a daughter, Barbara, a brother in Russia and a sister in New Jersey.

TRAINOR—JOHN BRETT TRAINOR, M.D., of 1517 South Main Street, Fall River, Massachusetts, died September 20, 1935, at St. Anne's Hospital.

Dr Trainor was born in 1868 and graduated from McGill University Faculty of Medicine in 1897. He joined the Massachusetts Medical Society in 1901 soon after opening an office in Fall River.

He was a Fellow of the American Medical Association, and served on the staffs of the Union Hospital and St. Anne's Hospital of Fall River. He was especially devoted to x-ray work.

He was affiliated with the Knights of Columbus, the Ancient Order of Hibernians, the Royal Arcanums, and the Catholic Order of Foresters. Dr Trainor is survived by his widow, Mrs Margaret E (Brady) Trainor, a sister, three brothers, and a nephew.

McQUAID—THOMAS BERNARD McQUAID, M D, of 42 Norwood Street, Everett, Massachusetts, died at

Webster Massachusetts September 19 1935 while on vacation.

Dr McQuaid was born in 1860 was a graduate of Holy Cross College and received his medical degree from the Dartmouth Medical School in 1896. He had practiced in Everett for more than thirty years and had served as physician to the local Board of Health.

He was a Fellow of the Massachusetts Medical Society and the American Medical Association.

Dr McQuaid is survived by a sister Miss Edith McQuaid and two brothers Michael McQuaid of Webster and Owen McQuaid of California.

BRYANT—JOHN BRYANT M.D. of 120 Sargent Road Brookline died September 19 1935. Dr Bryant was born in Cohasset, Massachusetts in 1880 the son of the late John Bryant and Charlotte Olmsted Bryant. His premedical education was acquired at the Milton Academy and Harvard College. His medical degree was conferred by the Harvard University in 1907. Early in his medical career he spent two years abroad in research work. On his return he served as assistant physician at the Robert Breck Brigham Hospital. He entered military service during the war with the title of captain and was advanced to the rank of major with assignment for duty at the surgeon-general's office in Washington.

After the war he was elected secretary to the American Gastro-Enterological Association and later became its president. Dr Bryant was especially interested in the problems of convalescence and had written several articles on this subject and was consultant to the Burke Foundation for Convalescents in New York City.

He was a Fellow of the Massachusetts Medical Society and the American Medical Association and a member of the New England Pediatric Society the Harvard Club the Somerset Club and the Society of Mayflower Descendants.

He is survived by his widow Mrs Adelaide Barnes Bryant, and two brothers Edward Bryant of Bolton New Hampshire and Owen Bryant of Tucson Arizona.

NOTICES

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday October 3 in the amphitheater of the Peter Bent Brigham Hospital Dr Henry A. Christian, Physician-in-Chief Hersey Professor of the Theory and Practice of Physio in the Harvard Medical School will give a medical clinic. To it are cordially invited practitioners and medical students. These clinics will be repeated on Thursdays from October to May.

On Saturdays to the wards of the Peter Bent Brigham Hospital from 10 to 12 staff rounds will be conducted by Dr Christian.

ERRATUM

The caption of the article by Milton S. Lloyd M.D. published on page 101, issue of July 18 1935 was incorrect. It should have read "The Clinical Classification and Early Diagnosis of Cancer of the Bronchus".

BOSTON UNIVERSITY SCHOOL OF MEDICINE SURGICAL CLINIC AT THE BOSTON CITY HOSPITAL

Friday September 27 121 Cheever amphitheatre. Dr William R. Morrison, Associate Professor of Surgery will present

1. Carcinoma of Distal End of Stomach Billroth II Operation.
 2. Carcinoma of the Transverse Colon with Partial Intestinal Obstruction. Resection with Intestinal Anastomosis.
 3. Acute Appendicitis with Peritonitis.
- Physicians and medical students are invited.

UNITED STATES CIVIL SERVICE EXAMINATION

Medical Supervisor (Psychiatric) \$5600 a Year
Department of the Interior

Applications must be on file with the United States Civil Service Commission at Washington D.C., not later than October 7 1935.

Applicants must possess the following qualifications:

1. They must be citizens of the United States.
2. Education. — They must have been graduated from a recognized medical school with a degree of M.D.
3. Experience. — 1. They must have completed either a regular rotating or a psychiatric internship of at least one year's duration or must have had experience considered equivalent to such internship.
2. In addition, they must have had not less than five years of responsible and progressive specialized experience in neuropsychiatry of which at least three years must have been in a senior administrative capacity in a mental hospital with not less than 300 daily average of patients under their care.
4. Age. — They must not have reached their fifty-third birthday on the date of the close of receipt of applications.

For more detailed information apply to the U.S. Civil Service Commission.

REPORT AND NOTICES OF MEETINGS

THE NEW HAMPSHIRE SURGICAL CLUB

The thirty-eighth annual meeting of the New Hampshire Surgical Club was held at the Farragut House, Rye Beach New Hampshire September 8 1935.

Dr Irving J. Walker Clinical Professor of Sur-

gery, Harvard Medical School, read a paper on Infections of Clean Operation Wounds

At the banquet, Dr. A. Warren Stearns, Dean of Tufts College Medical School, was the principal speaker

A golf tournament was held on the Abenaki links

The following officers were elected for the ensuing year: Dr. Robert J. Graves of Concord, President, Dr. Richard W. Robinson of Laconia, Vice President, and Dr. Ralph E. Miller of Hanover, Secretary Treasurer

WORCESTER DISTRICT MEDICAL SOCIETY 1935-1936

Wednesday Evening, October 9, 1935

PRESIDING

Dr Francis M. Rackemann Boston Chairman
Dr Richard P. Stetson Boston Secretary

THE CHAIRMAN *Gentlemen*—We have become very proficient in locating the trouble in the heart or brain or kidneys as well as in determining the nature of this trouble. We have learned about the clinical effects of lesions in all the different organs in the symptoms which result from disturbances of many different physiologic processes.

We have been much interested in the results of the disease process that is in pathology and in pathological physiology. Now I believe that the time has come to consider how these various diseases develop and what we do know or what we do not know about their cause.

At this meeting we have brought together a group of men who will give us a series of papers which ought to be very interesting from this new point of view. The first paper is by Dr Joseph H. Pratt, of Boston.

THE DEVELOPMENT OF PHYSICAL DIAGNOSIS*

BY JOSEPH H. PRATT, M.D.†

THE ability to make an anatomical diagnosis in many cases of organic disease of the hidden organs of the chest and abdomen by the skilled and systematic use of eyes, ears and fingers is a medical triumph of the first half of the nineteenth century. This epoch making development of medical diagnosis was inaugurated by two men, Corvisart and his pupil Laennec.

To John Collins Warren, first surgeon of the Massachusetts General Hospital, belongs the credit of introducing the first knowledge of heart disease to the physicians of America. Years later he told in his reminiscences how this came about. His account shows that as late as the early part of the nineteenth century not only were the methods of diagnosing heart disease unknown but the very existence of organic disease of the heart denied. For the light it throws on the development of physical diagnosis it is worth quoting over a hundred years later.

"In the year 1808 I was called to attend Governor Sullivan, who was then Democratic Governor of the State. * * * He was subject to frequent attacks of cough and difficulty of breathing, followed by copious expectoration of mucus, and frequently of blood in quantities. He had, also, violent palpitations of the heart, and great shortness of breath on going up stairs.

Under one of these paroxysms, his life seemed to be in danger, and I requested my father to see him in consultation. Among some remarks which he made he dropped a suggestion of a derangement of the heart. The moment he spoke the word, the whole subject flashed upon my mind. In 1801 and 1802, I had attended the lectures of Corvisart in Paris. He examined many bodies before us, used percussion and pointed at organic changes in this organ. Amidst a multitude of other concerns, this account of diseases of the heart had slipped my mind but was revived in the way I have mentioned.

"In England the subject was so entirely unknown, that a patient in Guy's Hospital dying of hypertrophy or as Corvisart called it, an eurism of the heart (the largest I have ever seen) was thought by the celebrated Dr Saunderson to have died of hydrothorax. The body was not examined by the physicians, but was left to me who was a surgeon's pupil and had no right to do it. With the aid of my friend Scuter, I examined it, and got out this enormous heart, which is now preserved in the museum of the Medical College.

"The symptoms of organic disease of the heart were not indeed, unknown, but they were attributed generally to other causes than derangement of the heart itself. I studied Governor Sullivan's case very carefully, and immediately discovered all the symptoms mentioned by Corvisart and some others.

*Read at the Annual Meeting of the Massachusetts Medical Society Section of Medicine June 4 1935.

†Pratt Joseph H.,—Physician in-Chief, Boston Dispensary. For record and address of author see "This Week's Issue," page 613.

"The Governor's illness made a great noise * * * Of course, there was much conversation about this notion of organic disease. All the older physicians, except my father, ridiculed this 'organic fancy' as Dr Danforth called it.

"In the month of December, 1808, the Governor died, with full symptoms of organic disease of the heart. Permission was given to examine the body thoroughly, and I invited the principal physicians in town, most of whom came. Among them were Drs Danforth, Rand, Jeffries, Dexter, my father, and Dr James Jackson. I proceeded to examine the body with tremulous confidence, knowing that some of the gentlemen present had a different opinion, and confidently expected I should fall into disgrace and ridicule.

"In the examination, I proceeded to point out the swelled limbs, purple visage, oedematous eyelids, the water in the thorax and abdomen, congested lungs, all of which belonged to the train of organic changes. But the heart was yet untouched. I then stated that the heart would be found enlarged, the left cavities increased in capacity, and the origin of the aorta, with its valves, ossified to a considerable degree. I then made a small aperture in the left ventricle, which was full of coagulated blood, and passing the finger into its cavity, sought for the aortic aperture. This was very much contracted, and surrounded by a bony ring extending through the aorta to the valves. The heart was enlarged, and its cavities extended, the parietes thickened. The other gentlemen examined successively, and were all satisfied of the change of structure.

"The subject was soon after illustrated by the appearance of Corvisart's work in this country. In England, the knowledge of these complaints became more slowly diffused than here."

The case of Governor Sullivan stimulated Dr Warren to the intensive study of heart disease. In 1809 he presented before the Massachusetts Medical Society the report of ten cases of heart disease with the postmortem findings. In this paper is described in detail the case of Governor Sullivan. It was not the custom at that time to make any examination of the body and so it happened that Dr Warren had been treating Governor Sullivan for some time without even inspecting his chest. Finally after a degree of insensibility had developed, "I seized this opportunity," he writes, "to examine the region of the heart, which had not been done before from fear of alarming the active and irritable mind of the patient. The heart was perceived palpitating obscurely about the seventh and eighth ribs, its movements were very irregular, and consisted in one full stroke followed by two or three indistinct strokes, and sometimes by an intermission corresponding with the pulse at each wrist. The pulsation was felt most distinctly in the epigastric region."

Publication of this excellent paper was delayed until 1813 when it appeared in the second volume of the Medical Communications and Dissertations of the Massachusetts Medical Society. A year previous the *New England Journal of Medicine and Surgery* was started and in the first volume a second series of cases of organic diseases of the heart was reported by Dr Warren. A case of aneurism of the aorta was described with an excellent drawing of the specimen obtained at autopsy. It is interesting to note that this patient was bled and blistered from the fall of 1808 until the spring of 1809 for pains in the right shoulder and arms without any examination of the chest. Finally the pains in the shoulder became "so severe as to induce Dr Eustis a friend of his family and Dr Bates his physician to make an examination of this part. When the breast was uncovered Dr Eustis observed with astonishment a small pulsating tumour on the right side of the thorax between the second and third rib at the distance of one or two inches from the sternum."

An examination of Dr Warren's case reports gives no indication that he attempted to use is probable that he received no personal instruction as a method of diagnosis. He states that he only attended a few of the lectures of Prof Corvisart at the hospital of La Charité in the year 1802 while a student in Paris. It is a pity that this great clinician

Singularly enough Dr Gates, the translator of Corvisart's great work, dedicated the American edition published in Boston in 1812 to the same Dr Danforth who four years before was so convinced that heart disease was an "organic fancy." Corvisart's method of percussion of the heart was very simple. A typical note in a case of "great enlargement of the heart" reported in this book is the following: "The thorax when struck sounded well on the right, but not the least on the left." In another case it was observed, "the region of the heart did not sound," and in a third, "The chest which sounded well in every other part was silent near the region of the heart." Percussion was made with the fingers of the whole hand and the force used was considerable. In addition to percussion Corvisart always noted the character and force of the apex beat and of the pulse. The rate in minutes was not noted.

Knowledge of physical diagnosis developed slowly. In 1817 in the first textbook of medicine to appear in America that of James Thatcher of Plymouth, Massachusetts, there is no mention of the examination of the heart or lungs. As late as 1825 Dr James Jackson in his textbook on the theory and practice of physic devoted only a few lines to percussion and auscultation. The only form of heart disease described is angina pectoris which is briefly described. The cause was not known. The condition was called sternalgia and it was not rec-

ognized that the heart was the seat of the disease. The words *augina pectoris* are not mentioned.

Modern medicine may with truth be said to date from the publication of Laennec's *Do l'auscultation médiate* in 1819. One of the first out- side of Paris to appreciate the value of auscultation and to attempt to employ it was Dr James Jackson the professor of medicine at Harvard and first physician of the Massachusetts General Hospital. His gifted son James Jackson Junior, under his father's tutelage was studying with zeal and with as much thoroughness as possible the auscultatory signs of disease. He had studied medicine less than two years when he wrote in his commonplace book on December 28, 1829 the report of a case of phthisis. I was invited this morning by Dr Fischer, physician of the House of Industry in South Boston to attend with him the examination of a woman who died the night before. I had seen the patient about a month ago. . . . The circumstances most observable at that time and for which I was invited to see her, were that the metallic tinkling had been heard in her chest through the medium of the stethoscope. This was observed upon the left side of the thorax. . . . It was just below and partly upon the scapula, and also, if I did not mistake over the space between the scapula and spine. On applying the instrument, I heard it very distinctly several times. It was audible immediately upon the termination of inspiration as expiration commenced and thus with great regularity. Dr Fischer likened it to the sound produced by the blowing of air into a wet bladder. Another gentleman thought it most like a drop of water falling into a glass bottle half filled with fluid. For myself I should say it was something between the ticking of a watch and the sound produced by striking a small bar of steel upon any resounding body. Whatever this sound may have resembled, however it was most unequivocally metallic in its nature."

An autopsy was carefully performed and young Jackson wrote a detailed protocol occupying nearly four pages of printed text. The (left) upper lobe presented at once the appearance of a large cyst, and upon handling and tapping this with the finger we felt assured that it was a large cavity filled with air and fluid and we again heard a faint metallic sound. . . . Upon opening into the cavity we found nearly a pint of purulent fluid of a cream like consistence. The walls of the cyst were one third of an inch in thickness. . . . At the end of the protocol he made the following comment. One practical advantage to be derived from this examination is, that pneumothorax does not always exist when the metallic tinkling is heard. . . . "Laennec mentions two cases similar to this (37-38 1st edit) entitled '*Tontement métallique dans une vaste excavation tuberculeuse*'"

It is astonishing that the above carefully recorded facts were observed by a youth of nineteen. He made as thorough a physical examination as he could, then performed a complete autopsy and finally consulted the literature. This case report shows that auscultation of the lungs was practised as early as 1829 in Boston and with the aid of a stethoscope, and the results obtained were compared with the pathological findings at autopsy.

Young Jackson continued the study of auscultation with great zeal and industry in Paris under the great Louis and also received personal instruction from the distinguished professor Andral. A memoir of this brilliant young American student whose untimely death at the age of twenty-four was a great loss to the science of medicine was published by his father in 1835. This book contains much of present-day value on physical examination of the chest and abdomen. It can be read with profit by all students of medicine. Dr H. B. Jacobs of Baltimore says of this remarkable work "I scarcely know any book which is more of an inspiration to the medical student, more of an incentive to hard work and to high ideals than the little story of the life of this young man."

James Jackson Senior was an eager student of auscultation. In September 1831 in a letter to his son then in Paris he said "I want to know more what you have learnt about auscultation in diseases of the chest" and again on January 6, 1832 he wrote of the difficulties he had in the use of the stethoscope "I scarcely expect to overcome them—yet I expect you to do it."

It can be seen from these historical notes that John Collins Warren was the first physician in this country to recognize the existence of heart disease. The physical examination in diseases of the heart introduced the new knowledge brought to light by Corvisart into America that there was a relation between the size and action of the heart and the well known symptoms dyspnea and dropsy. Twenty years later James Jackson and his son were eagerly studying the relation between sounds heard on listening to the chest and diseases of the lungs especially phthisis. James Jackson Junior while in Paris made the important discovery that prolongation of the expiratory sound was a symptom of what was then regarded as the early stage of consumption. Up to that time the attention of auscultators on listening to the breath sounds was chiefly devoted to the inspiratory phase of respiration.

Auscultation was first taught in Boston by Henry I. Bowditch. He was the friend and fellow pupil of James Jackson in Paris. Thoroughly trained in physical diagnosis by Louis he was well equipped to give instruction in this subject. According to Dr Jackson young Bowditch was inspired by the "same desire for knowledge and love of truth" that character-

ized his son. For about twenty years from 1835 onward he gave personal instruction in physical diagnosis to a small group of students annually. The notes of his lectures in manuscript form are in the Boston Medical Library. In 1846 he published the first textbook in America on auscultation and percussion. It was entitled "The Young Stethoscopist or the Student's Aid to Auscultation," a title far too modest for an admirable work that can be studied by all practitioners as well as medical students with profit.

The great advance in the first third of the present century in diagnosis is the ability to recognize at an earlier stage serious disease, such as pulmonary tuberculosis and cancer of the digestive tract and gall bladder disease by means of the roentgen ray, and cancer of the esophagus and stomach, urinary bladder, lower portion of the intestine and the bronchi, with the aid of the endoscope, by direct inspection.

Recent discoveries have lessened confidence in negative physical examinations of the chest and abdomen. It should be common knowledge that the percussion and auscultation of the lungs may reveal nothing abnormal when an x-ray film may show evidence of pulmonary tuberculosis in even an advanced stage. Hence a patient should never be assured positively that he does not have tuberculosis of the lungs until a good x-ray film has been made with a negative result. Formerly cancer of the stomach was rarely diagnosed before a tumor mass could be palpated. Now by means of the relief method of studying the gastric mucosa with the x-ray and by gastroscopy it is often possible to recognize this disease at a stage early enough to permit some hope of cure.

In examining a patient one only sees what he looks for. Unless an observation appears to have some significance, little attention is paid to it and little or no impression is made on the memory. The reason physicians one hundred and thirty years ago did not examine the chest was doubtless due to the fact that such an examination as they could make very rarely revealed anything of significance to their minds. The diagnosis may have been "writ large" on chest or abdomen but if in an unknown language it made no impression on the observer.

Doubtless physicians for centuries had been consulted for headache by patients afflicted with acromegaly but the large nose and massive jaw, the thick lower lip, the short hands with their broad stubby fingers made little impression upon observers until Pierre Marie demonstrated the connection between this peculiar bodily structure and tumors of the hypophysis.

At an earlier period Addison showed the connection between brownish pigmentation of the skin and mucous membranes, and disease of the adrenal glands. From that time onward such pigmentation was sought for and described with care, simply because its possible significance

was for the first time understood. The same was true in regard to exophthalmos when its association with a particular type of goitre was discovered by Parry and Graves. Recently discovered new facts in the domain of endocrinology make various types of obesity appear in a new light. Now that the association of a rapidly developing obesity with purple striae of the skin, hypertension, hirsutism, amenorrhea and a high blood pressure has been shown by Harvey Cushing to be related to small basophilic adenomas of the pituitary gland, cases of obesity in all parts of the world presenting any of these characteristics are receiving a more careful physical examination than previously. Within the past three years a number of cases of tumors of the adrenal cortex have been reported which presented a similar clinical picture. This has been the result of a more thorough study of unusual cases in which obesity was a feature. Rapid emaciation with cachexia has likewise been investigated more thoroughly since it has been recognized as the clinical expression of great deficiency of pituitary secretion, the clinical condition produced being known as Simmonds' disease. Likewise the details of the physical structure and confirmation of stunted children and dwarfs have been observed and noted down since the discovery was made that certain types are due to pituitary insufficiency.

Some special diagnostic procedures have increased the understanding of functional disorders with the result that inspection and palpation are of more aid in diagnosis at the present time than ever before in diagnosis. A notable example is furnished by the polygraph of Sir James Mackenzie and the electrocardiograph. Possessed of the new knowledge gained from the use of their instruments it is possible usually by listening to the heart and palpating the radial pulse to recognize sinus arrhythmia, extrasystoles, auricular fibrillation, and heart block. The orthodiagraph has been helpful in developing the technic of cardiac percussion.

The importance of the physical examination alone in detecting early disease is often overrated. In recognizing beginning heart failure as Sir James Mackenzie taught, subjective symptoms generally precede objective signs. On the other hand in early endocarditis a systolic murmur is usually the first sign of the disease. Only examinations repeated either daily or at frequent intervals may reveal a pericardial or pleural friction rub or the appearance of fluid in pleural or pericardiac cavities. Physical signs in association with early subjective symptoms characteristic of a disease often clinch the diagnosis. A favorite example of a pathognomonic physical sign is the crepitant râle of early pneumonia. Localized râles in the upper part of a lung with bronchovesicular breathing are almost diagnostic of pulmonary tuberculosis when pres-

ent in a patient with cough and slight fever of some weeks' duration. Similar examples might be cited, such as the value of the consonating character of the râles in the diagnosis of bronchopneumonia.

The great value of a negative physical examination in making a diagnosis is largely by exclusion in a patient who presents marked subjective symptoms and should be emphasized.

The history of the development of physical diagnosis shows clearly that deviations from the normal are either unnoticed or attract little attention until their significance stands revealed. It is probable that advance in knowledge will enable physicians, one hundred years from now, to discover much of diagnostic value on the physical examinations of their patients that is now passed unnoticed. The gain in the last century has been enormous. It is possible that the next may show an even greater advance.

DISCUSSION

THE CHAIRMAN Before I open the discussion I would like to ask all those who want to talk about these papers to come forward and stand on the platform so that everybody can hear.

DR. ROBINALD FITZ, Boston *Members of the Section*—I think we have heard a very helpful paper. Personally I never can hear anything of medical history without feeling humble. It does one good to realize by what sort of men our present quantity of physical diagnosis has been developed. In Boston it must always give us pleasure to hear the names of Warren, Jackson and Bowditch repeated lest we forget what those men did to build up our present knowledge.

Dr Pratt has brought out another interesting point in his paper that is worth mentioning. In the early days pathological examinations were relatively unimportant. As the number of pathological examinations increased so increased clinical and pathological correlation and the accuracy of physical diagnosis. Carefully conducted pathological examinations are still most important particularly in hospital cases which claim to train interns.

Dr Pratt says that a generation ago physicians were apt to be more expert in physical diagnosis than today because they were not handicapped by the mechanical aids that have crept in. There is no doubt that the mechanical aids to diagnosis may be helpful and will continue to be employed. It is important to remember however that one can learn much by physical examination. New methods may be misleading unless they are most carefully controlled. In this connection I am sorry that Dr Pratt did not mention the warning of Oliver Wendell Holmes. About the time the stethoscope was introduced Dr Holmes wrote the story of the young girl who fell ill and of the young doctor who took care of her. The young doctor listened very carefully with his stethoscope and heard queer noises in the patient's chest. He called in one of his older colleagues who looked at the young lady and soon discovered that the trouble was that she had fallen in love with the young doctor and the queer noises in her chest were due to a couple of flies in the bell of the stethoscope.

"Now use your ears, all that you can,
But don't forget to mind your eyes,
Or you may be cheated like this young man,
By a couple of silly ahnornel flies

DR. F. VAN NUTS, Weston, Mass. Dr Pratt quotes a significant statement, "that in physical examination we see only what we look for." A corollary of this statement is that we look at a disease not as a whole but at its most familiar facet. Inasmuch as most diseases have not one but many facets the etiological, the chemical, the anatomical, the histological, it behooves us to broaden our conception of each disease.

This conception itself varies with each medical generation, and indeed with the physician's nationality. The endemic typhoid of a generation ago presented clinical aspects which physicians will never see again. The changing scientific viewpoint today upon polynneuritis is totally different from that of pre-war days.

We see only what we look for. Hence the key stone of all physical examination is pathology. Lewellyn Barker writes, that, "once the main outlines have been mastered it is easy to fill in with finer material. These 'main outlines' mean pathology."

One concept of yellow atrophy, once a rare disease has been completely remodeled. Formerly the symptoms themselves loomed large. The disease was a very narrow one. It came usually after pregnancy and ran to a speedy death. Today the conception of the disease has been widened greatly. The symptoms are relegated to second place, and the pathological picture of a toxic hepatitis with its various subsequent events, Barker's "Finer material" stands to the foreground in our diagnosis.

You remember Keats' Sonnet

"Then felt I like some watcher of the skies
When a new planet swims within his ken."

Just as does a general medical practitioner watch day by day for one of the rare findings in physical diagnosis. One keeps hoping that he may see the miliary tubercle of the choroid, the amaurotic "cat's eyes" of a sarcomatous retina, the trident hand of xanthodermia, the pulsating intercapular arteries denoting aortic aneurism, a motor aphasia in a left sided hemiplegia.

The pleasure of ones first encounter with the thalamic syndrome or with the "glove pigmentation of pellagra, the sulphur granules in actinomycetosis, the signs of athenic bulbar paralysis—the discovery of any one of these keeps physical examination fresh and eager. I read once of a policeman who couldn't let go of his prisoner's arm because of a tumor in the officer's corpal carpalus. Probably not one of us will ever meet such a case but if he does he will feel like a collector of rare Americana who picks up a copy of Mark Twain's "Elkathetan Fire-Side Conversation in a stall out side a junk shop."

Dr Pratt spoke of new signs of physical findings. Of course these signs always have faced us. It is this significance which counts. We older men knew pulmonary edema as a clinical entity. It is only lately that we recognize it as a symptom of left heart failure.

In "Monographic Medicine of 1916" I find no distinction drawn between angina pectoris and coronary occlusion and yet today they present two distinct pictures.

In my house-officer days cerebral hemorrhage was very familiar. Cerebral thrombosis was almost unrecognized. Death from cerebral hemorrhage was supposed never to be sudden. It always was a matter of a day or so. Later we find it not infrequent within an hour after intraventricular hemorrhage.

DR. HENRY A. CHRISTIAN, Boston I would like this opportunity of making a plea for the stillness

tion of the very simple methods of physical diagnosis, the very simple laboratory methods that any physician can carry out, not because they are makeshifts for more complicated methods but because the latter often are not needed, if the simple methods are intelligently applied. I have had occasion recently to bring together some observations on what I call the lag between clinical diagnosis and x-ray confirmation of the diagnosis, pointing out a number of circumstances under which the simple methods of history-taking and physical examination can anticipate the diagnosis by days, weeks or months before the x-ray will show the changes.

I want too, to cite an example of how not doing a very simple thing led to an illness of a year and a half on the part of a patient and the expenditure of a very considerable amount of money. This patient was ill with diarrhea. One of his early contacts with modern medicine was a laparotomy to find out why

he had diarrhea. They did not find out. After eight or nine months more of suffering the patient had x-ray studies of the gastrointestinal tract and then it was found that he had proctocolitis. Now and only now was his stool examined, amebae were found, he was treated with emetin, in twenty-four hours he made a marvelous change, and in a day or two he was practically well.

It is these simple methods, intelligently applied, that give us a vast amount of important information and it is not at all necessary to have complicated laboratory and instrumental methods to arrive at many diagnoses. Obviously, if the simple methods fail to make a diagnosis, then you should proceed to use the more complicated ones and intelligently correlate all of the evidence.

(Dr. Chester S. Keefer of Boston read his paper entitled "The Etiology of Chronic Arthritis".)

THE ETIOLOGY OF CHRONIC ARTHRITIS*

BY CHESTER S. KEEFER, M.D.†

ONE of the most important factors in the prevention or control of any chronic disease is a complete understanding of its etiology. At the present time there is no general agreement regarding the cause of various forms of chronic disease of the joints, but it is well for the student of this group of disorders to pause from time to time and assess in a critical fashion the information that has accumulated. In this paper I propose to consider the various hypotheses that have been advanced in an attempt to define the etiology of chronic arthritis. It is not my purpose to make any pretense at a comprehensive review of the extensive literature dealing with this question. The discussion will be confined more or less to a consideration of those facts which deal with the main views regarding the pathogenesis of degenerative and rheumatoid arthritis.

TERMINOLOGY

In any discussion of chronic arthritis it is highly essential that there be a clear understanding of the terms which are used. Great confusion exists and, since there is a certain degree of looseness in the precise definition of diseases of the joints, it is only natural that misunderstandings should arise from any discussion in which the type of disorder is not defined with care. Another source of error arises when conclusions regarding etiology are drawn from the benefits that seem to follow various therapeutic measures. It is important, moreover, to discriminate between the clinical features that are primary and those which contribute to the symptomatology of the disorder.

It has been well said that thought concerning the etiology of arthritis is clouded by the tendency to confuse primary and contributory factors.

DEGENERATIVE ARTHRITIS

This term is used synonymously with osteoarthritis and hypertrophic arthritis. The pathologic picture is characteristic so that the condition can be readily discriminated from other maladies of the joints. It is characterized by (1) fibrillation, erosion and destruction of the cartilage with attempts at regeneration, (2) increased vascularization and thickening of the subchondral bone, fracture, attempts at repair with new bone formation, islands of cartilage and cysts in the cancellous bone, (3) the formation of exostoses, (4) normal synovial membrane or slight thickening of the capsule with papillary projections of synovial cells into joint cavity. In other words, it is a condition that begins in the articular cartilage and involves the underlying bone and synovia secondarily. As a result of personal observations, together with those of others^{1, 2, 3, 4, 5} it now seems evident that degenerative arthritis is not a systemic disease with joint manifestations, that affects many of the joints with equal intensity, but its occurrence in the different joints of the body can be explained on a basis of various factors producing injury, excessive "wear and tear" or trauma to the articular surfaces. A careful analysis of the different factors in the individual case will enable one to discover both the predisposing and accelerating conditions that produce the changes arising in the affected joints. This question of the pathogenesis of degenerative arthritis has been discussed by me previously and for the details supporting these statements the original paper may be consulted.

RHEUMATOID ARTHRITIS

This term is used synonymously with atrophic or infectious arthritis. It is a disease which be-

*From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard) Boston City Hospital and the Department of Medicine, Harvard Medical School, Boston, Mass. Read at the Annual Meeting of the Massachusetts Medical Society, Section of Medicine, June 4, 1935.

†Keefer, Chester S.—Assistant Professor, Harvard University Medical School. For record and address of author see *This Week's Issue*, page 689.

gins in the synovial membrane and periarticular tissues and involves the articular cartilage and bone secondarily. The histologic picture of the synovial membrane and periarticular tissues is characterized by increased thickness and proliferation of the synovial membrane, and infiltration with lymphocytes and plasma cells in the subsynovial layer. In some areas these cells accumulate about blood vessels, in others there is no such arrangement. As the proliferation of the synovial membrane increases and advances, it grows inward from the periphery of the joint and becomes adherent to the articular cartilage. Following this, a sequence of events occurs depending upon the severity and duration of the process and physical activity of the patient. The various pathologic features are summarized in table 1.

TABLE 1

PATHOLOGIC LESIONS IN RHEUMATOID ARTHRITIS

Primary	Secondary	Miscellaneous
Synovitis	Destruction	Lymphoid
Periarticular	of Cartilage	Hyperplasia
change with	Atrophy of Bone	Calcification of
and without	New Bone	Blood Vessels
subcutaneous	Formation	Amyloidosis
fibroid	Subluxation	Growth
nodules	Ankylosis—	Disturbance
	Fibrous	Pigmentation of
	Bony	the Skin
	Muscular Atrophy	

While many theories have been advanced to explain the etiology of rheumatoid arthritis none of them meet with universal approval or acceptance. For purposes of discussion there are three which merit special consideration. They are as follows: (1) the unitarian theory, (2) the infectious theory and (3) the 'eclectic' theory. It should be insisted upon that any theory which attempts to explain rheumatoid arthritis must account for the development of the lesions in the synovial membranes and periarticular tissues. After all these are the essential and characteristic lesions of the disease and they are present in all proved cases. The factors that tend to exaggerate symptoms and influence the course and progress of the disease once it has been established, may be somewhat different from the primary or inciting cause. These must be studied carefully and separated in so far as it is possible. It is necessary then to examine the evidence that has been brought forth in an attempt to explain the anatomical lesions that are so characteristic of this disease.

THE UNITARIAN THEORY

The proponents of this theory maintain that both rheumatoid arthritis and degenerative arthritis are due to the same etiologic agent or group of agents and that the differences are due to factors other than causation. In other words the factors determining the type of arthritis

depend upon "trauma, foci of infection the involutional changes of the menopause and the habits of the patient." The reasons for advancing such a theory are due to the observations that the pathologic changes which are seen in the joints of many patients with arthritis have the characteristic changes of both types. This has been referred to by some physicians as a mixed type of arthritis. To find the characteristic features of both types of arthritis in certain patients is not surprising. This can be readily explained and does not necessarily mean that both types are caused by the same factors.

When the incidence of degenerative changes in the joints is studied in a miscellaneous group of individuals regardless of whether they have symptoms referable to their joints it is found that the alterations increase in frequency as age advances and in individuals over forty years old it is difficult to find joints which are absolutely normal. This degenerative process begins in the cartilage and the synovial membrane shows no lesions. If a patient with degenerative changes in the joints develops rheumatoid arthritis then the lesions of both types will naturally be present. If on the other hand there are no degenerative changes in the joints of the patients who develop rheumatoid arthritis then the disorder will be synovial and periarticular in character. Ample evidence for this explanation is forthcoming when the joints are examined histologically. That is to say no one can mistake the characteristic lesions of one type of arthritis for the other. The course of events is quite different in the development of the two types of joint disease, and for the reasons cited it is not possible to accept the unitarian theory of the origin of rheumatoid and degenerative arthritis.

THE INFECTIOUS THEORY

This theory of the origin of rheumatoid arthritis has attracted widespread attention especially in this country. The presence of slight fever, leucocytosis, increased red blood cell sedimentation rate, inflammatory lesions in the synovial membrane and periarticular tissues, enlargement of the lymph nodes in the region of the joints and the presence of synovial fluid with all of the characteristics of an exudate have suggested this possibility. In addition the occurrence of positive agglutination and precipitin reactions to the hemolytic streptococcus in the blood serum of patients with rheumatoid arthritis has suggested that infection plays an important part in the pathogenesis of the disease.

To explain the lesions in the synovia on a basis of infection three general ideas have developed: (1) The arthritis is a true metastatic lesion from a focus of infection. (2) It results from the action of "toxins" which are absorbed from a focus of infection. (3) It results from a reaction of sensitized tissues to microorganisms or their products.

Before discussing these three views it is desirable to review briefly the theory of focal infection in general, especially as it applies to arthritis

THE RELATIONSHIP OF FOCAL INFECTION TO ARTHRITIS

There is, perhaps, no subject which has been discussed more often in its relationship to arthritis in general than focal infection. It has been frequently misunderstood and misrepresented. Much of the confusion has arisen from a lack of understanding of the general principles involved in focal infection and as a result of the enthusiasm or pessimism in the interpretation of the end results that have been obtained in patients with arthritis following the removal of foci of infection. A most careful and comprehensive review of focal infection and elective localization has been prepared by Holman⁸. In America, the subject of focal infections was popularized by the observations of Billings⁹. He defined a focus of infection as "a circumscribed area of tissue infected with pathogenic microorganisms". He further emphasized the fact that a focus of infection may give rise to intoxication or focal infection, which meant invasion from a focus, and it is known, as Holman states, that a focus may be latent or inactive.

Before one can accept arthritis as a condition due to focal infection, it is necessary to establish three things: first, that there exists or has existed a focus of infection, secondly, that the focus of infection is bacterial in nature and, therefore, capable of disseminating toxin or organisms, and, thirdly, that infection or damage to the joints has resulted from a dissemination of material from the focus of infection. In some cases it is possible to establish these three facts, in others it is questionable. For example, everyone is familiar with the cases of arthritis which follow streptococcal infections of the uterus with metastatic lesions in the joints. In these cases, the focus of infection is in the uterus and the organisms have been disseminated through the blood stream to the joint tissues so that the same microorganism may be cultivated from both places. Furthermore, it is common knowledge that following a streptococcal infection of the tonsils, as in scarlet fever, an arthritis may appear which is non-suppurative and the joint tissues do not contain organisms. In these cases, the focus of infection is in the tonsils, but it is not always clear just what the mechanism of the joint inflammation really is. To be sure, it has been attributed to the dissemination of toxic bacterial products or to an allergic response upon the part of sensitized tissues to the disseminated bacterial products. That there is some close as-

sociation between the lesion in the throat and the joint manifestations in the cases cited, there seems to be little doubt. The precise mechanism, however, remains obscure.

When arthritis appears without a preceding acute infection and becomes progressive and chronic, the question then arises, is the condition in the joints the result of the dissemination of bacterial products from a focus of infection which may be latent, subacute or inactive? In the first place, it is necessary to determine whether a focus exists and to consider what criteria of infection are present before such a focus can be considered as a contributory factor to the arthritis. It is only after a most careful history and physical examination that one can feel reasonably certain that a focus of infection exists. Once it has been established that a focus of infection is present, the question then arises, is this focus in any way contributory toward the arthritis and, if so, what is the mechanism by which it exerts its effect? One of the criteria upon which the theory of focal infection is based is the fact that following the removal of the primary focus there may be an exacerbation of the secondary focus or a disappearance of the clinical condition. Every one has had the experience of observing the temporary disappearance or exacerbation of the symptoms of arthritis following such procedures, but the interpretation of such phenomena is most difficult. When there is neither improvement nor an exacerbation of the arthritis following the removal of the suspected focus, it may mean that the focus is either not the cause, or that the arthritis is so firmly established that the removal of the primary focus has been of little help. The failure to observe improvement of the arthritis following the removal of foci, the presence of arthritis without demonstrable foci of infection, the improvement of arthritis without the removal of foci, the common occurrence of foci in patients without arthritis and the inability to obtain organisms from the joints have been the main arguments which cast doubt upon the validity of the theory of focal infection and its relation to rheumatoid arthritis. Moreover, it has been frequently claimed that the improvement which follows the removal of a focus may be due to a general stimulus resulting from the removal of one cause of a lowered systemic resistance.

Aside from the cure of the patient, other criteria have been used to establish the relationship between focal infection and arthritis. It has been stated already that the onset of arthritis following an acute infection is important and the evidence of disease in a tissue which has preceded the arthritis is helpful. But, in many cases, the infection has occurred a long time before the patient is seen and the local evidence for infection may be questionable. In-

deed, many patients give no history of a preceding infection. It has been necessary therefore, to use other methods to establish the relationship between the hypothetical focus and the joint disorder. The finding of organisms in the blood stream or the synovial fluid would be of great diagnostic help. It should be remembered, however, as Holman has pointed out, that the high invasive power of such organisms as streptococci requires caution in accepting the presence of streptococci in the blood as of overwhelming importance in the etiologic diagnosis of such conditions as chronic arthritis.

A most important contribution in this regard is that of Lichtman and Gross¹⁰ who reported finding streptococcemia in an average of 6 per cent of 5,233 blood cultures in at least nine diseases, such as, acute rheumatism with polyarthritis, chronic rheumatic cardiovascular disease, rheumatoid arthritis, aplastic anemia, pernicious anemia, leukemia, colitis, meningococcus meningitis and pyelitis and pyelonephritis. In view of these findings, together with the controversial data on the blood cultures in chronic arthritis which will be discussed presently, it is seen that the blood culture may not be helpful in all instances in establishing the relationship of foci of infection to arthritis.

Another method which has been used in the study of the etiologic relationship of microorganisms recovered from foci of infection to arthritis is the study of the blood serum for the presence of antibodies (agglutination reactions, complement fixation reactions and precipitin reactions^{11, 12, 13, 14, 15}). The results as regards the specificity of these reactions are highly controversial. Even those investigators who have found serological reactions to various microorganisms in the blood serum of patients with arthritis freely admit that they are not specific for any one strain of organisms. When reactions to one strain are present they are usually present against other strains as well. It is for this most important reason that it is difficult to assign an etiologic relationship between organisms isolated from a focus of infection and the arthritis in an individual case.

Finally, a third method has been used to determine the etiologic relation of foci of infection to arthritis, that is, to test the patient's skin sensitivity to the bacteria or bacterial products which have been obtained from the focus of infection.^{16, 17} The literature regarding this subject has been reviewed previously and need not be repeated here.¹⁸ It is well to recall, however, that results of these studies are most difficult to interpret in so far as causation is concerned. It has been shown that patients with arthritis will have positive skin reactions to microorganisms or their products in a slightly higher percentage of cases than in individuals without arthritis. But in view of the fact that

all patients with arthritis do not show positive skin reactions to products of the microorganisms and they may react to organisms that are not obtained from foci of infection, it is difficult, at the present time, to accept the etiologic relationship of foci of infection to arthritis from studies of this kind.

It is seen, then, that the infectious theory of the etiology of rheumatoid arthritis has as its basis the theory of focal infection. We may now return to the original question. Can the lesions in the synovia be explained on the basis of focal infection?

IS RHEUMATOID ARTHRITIS A TRUE METASTATIC LESION FROM A FOCUS OF INFECTION?

From what has been said, it would be necessary in order to answer this question in the positive to demonstrate the following facts: (1) that a focus of infection exists, (2) that the tissues of the joints or the synovial fluid contain the same organisms as those obtained from the primary focus. It would also be of importance, although not absolutely essential, to find organisms in the circulating blood. It is known that some investigators have felt that these facts have been demonstrated. However, there is no general agreement regarding the presence of microorganisms in the synovial fluid or tissues and no one investigator has been able to obtain absolutely consistent results.^{19, 20, 21, 22, 23} Until it is possible for all investigators to find organisms in the synovial tissue or fluid it cannot be accepted that rheumatoid arthritis is the result of metastatic lesions from a focus of infection.

IS THE REACTION IN THE JOINTS IN RHEUMATOID ARTHRITIS DUE TO THE DISSEMINATION OF TOXIC PRODUCTS OR A HYPERSENSITIVE REACTION TO THE PRODUCTS OF THE STREPTOCOCCUS?

In view of the fact that it is not possible to isolate microorganisms from the synovial fluid or tissues about the joints in cases of rheumatoid arthritis, it has been postulated that the reactions in the joints are due to the response of toxic products or a hypersensitive reaction to the products of the organism. This is also suggested by the observation that some form of joint disease such as is seen in serum sickness or postdysenteric arthritis, and in these cases it is known that the intra-articular reaction is not due to the presence of microorganisms.

In order to test this hypothesis, the patients with rheumatoid arthritis have been tested with various toxic products from the hemolytic streptococcus to determine whether they show skin reactions which might be interpreted as being either hypersensitive reactions or susceptibility to toxins. While it has been shown that a high percentage (70-80 per cent)^{24, 25} of individuals with rheumatoid arthritis react to these products, whereas only about 40 per cent of normal individuals will show the same reactions it is

not clear that this difference is of etiologic significance. It would be more impressive if all patients with rheumatoid arthritis showed positive reactions and fewer patients without arthritis showed no reaction. It might be argued that patients with other allergic diseases often fail to show positive skin reactions and yet they are known to be sensitive to the antigens injected, and it also can be stated that some individuals will show reactions in the skin and not elsewhere. However, in the face of the evidence as it exists today, it is not possible to accept the allergic hypothesis as proved. This mode of approach to the study of rheumatoid arthritis requires further investigation.

One of the strongest arguments in favor of the infectious theory of rheumatoid arthritis is the presence of agglutinins and precipitins to hemolytic streptococcus in the blood serum.^{12 13 14 15} The precise significance of these findings cannot be stated with certainty at present but they are present frequently enough and absent in the control patients who have been studied so that their presence cannot be disregarded as a chance or insignificant finding. There are two questions to answer in this regard, first, are these reactions a response to streptococcal infection or, secondly, are they responses to some process which gives rise to changes in the blood serum which are capable of causing the serological reactions observed? Such serological reactions of a non-specific nature as regards etiology are seen in syphilis and in typhus fever. It is important, therefore, that these serological reactions be investigated much more thoroughly before drawing definite conclusions regarding their etiologic significance.

There are, thus, many facts suggesting that rheumatoid arthritis is an infectious disease. The final proof, however, is lacking and will only be acceptable when the mechanism by which infection produces its effects can be proved beyond doubt.

THE ECLECTIC THEORY

This theory is the one sponsored by the American Committee for the Control of Rheumatism.²⁴ It is somewhat complicated and difficult to understand since a wide variety of factors are considered to be of importance in the etiology of rheumatoid arthritis. For that reason it is difficult to advance arguments for or against it. One gains the impression, from the various discussions of this theory^{25 26}, that rheumatoid arthritis results from an "imbalance" or "dysfunction" of three systems, namely, the nervous system, the gastrointestinal system and the peripheral vascular system. It has not been made clear just how this so-called "imbalance" operates to produce chronic inflammatory reactions in the synovial membranes and periarticular tissues with exudates in the

joint cavities but it is profitable to examine the evidence for "dysfunction" in these three domains as etiologic factors in the production of rheumatoid arthritis.

GASTROINTESTINAL DISORDERS

It has been claimed that gastric anacidity, atonic dilatation of the colon and carbohydrate indigestion are commonly found in patients with rheumatoid arthritis and are of etiologic significance.

Bloomfield and I²⁷ pointed out a few years ago that when the data on the incidence of gastric anacidity in chronic arthritis were corrected for age, it was no more common than in a group of control patients of the same age and without arthritis. It would seem unlikely, then, that a disturbance in gastric secretion could be of any etiologic significance. The same conclusions were reached by Miller and Smith²⁸ who have discussed the subject with considerable penetration.

Atonic dilatation of the colon has been found in a number of patients with arthritis by Pemberton and Pierce, Fletcher and Graham and others.^{29 30} This has been attributed to defective nutrition and "frequently plays a part in the development and course of chronic arthritis." When an adequate series of controls is studied, such as has been done by Bauer³¹, Archer³² and Haft³², there is no evidence to support the view that the observed abnormalities in the colon, if they really are abnormalities at all, are in any way related to rheumatoid arthritis unless they are a result of the illness. Furthermore, in a study of the same question by Nissen³³ it was found that the atonic enlargement of the colon appeared gradually in patients with chronic disease, especially in individuals with arthritis. This occurred without changes in the diet, but in individuals who were unable to take exercise. When exercises were given, the size of the colon changed. It should be added that changing the technique of the barium enema may also bring about decided alterations in the size of the bowel. Nissen³³ has examined the colon of these patients with a proctoscope and found no abnormalities, and I have studied the bowel of four patients who died with rheumatoid arthritis and was unable to find any anatomical evidence of atrophy or any other disturbance either by gross or histologic examination.

It would appear, therefore, that the evidence for intestinal dysfunction as a factor in causing rheumatoid arthritis is far from convincing so far as demonstrable changes in the colon are concerned.

CARBOHYDRATE INDIGESTION

Intestinal carbohydrate dyspepsia is a condition in which there is evidence of bacterial

fermentation of starches. It has been observed in patients with rheumatoid arthritis³⁴ but also in many other conditions, as well as occurring by itself so that such a state cannot be etiologically for rheumatoid arthritis. Since the recognition of intestinal carbohydrate indigestion is dependent upon finding excess gas formation over normal following the incubation of a culture of stool, the presence of an excessive number of starch granules in a fresh specimen and a stool that is strongly acid in reaction, it would be necessary to show that this condition is present in patients with rheumatoid arthritis and not present in normal individuals under controlled conditions. It should be emphasized that the condition can be produced at will by giving a cathartic. From the observations of Hurst and Knott³⁵, one is led to believe that this condition is a common occurrence in a variety of individuals who complain of intestinal gas and noises, but no mention is made by them regarding the presence of arthritis in such individuals. From this discussion it is seen that there are no constant deviations from the normal when the gastrointestinal tract of patients with rheumatoid arthritis is studied. Moreover, when changes in function are seen they usually follow rather than precede the arthritis and, since similar changes are observed in patients without arthritis it is difficult to accept the hypothesis of dysfunction of the intestinal tract as a cause of rheumatoid arthritis.

DISTURBANCES IN THE PERIPHERAL VASCULAR SYSTEM

Since many patients with rheumatoid arthritis have (1) cool hands with increased sweating and an abnormal response to cold, (2) decreased capillary circulation in the nail beds and a delayed removal of sugar from the blood (3) improvement of symptoms following procedures causing vasodilatation, it has been postulated that there is a reduction of the blood supply to the joints which is responsible for the development of the arthritis.

Now, when the synovial membrane of a joint with rheumatoid arthritis is studied with a microscope there is no evidence of a decrease in the blood supply. Indeed, one is impressed by the rich blood supply and the presence of many wide open capillaries. When the capillaries of the skin or nail beds of patients with rheumatoid arthritis are studied, there are no consistent findings^{37, 38, 39} and when alterations in the number and the rate of the flow of blood are present, they may be exhibited early, late or not at all (Hench, Weil, Kovacs) and it has recently been pointed by Bordelev that the blood flow in the capillaries of the normal skin is intermittent so that this must be taken into account in evaluating studies of the capillaries

in patients with arthritis. If a decrease of the blood supply to the joints is responsible for the development of rheumatoid arthritis it is not a little curious that diseases in which there is no question of a decrease of blood supply to the extremities are so infrequently associated with arthritis, such examples are (1) occlusion of the larger vessels as in thromboangitis obliterans arteriosclerotic occlusion (2) Raynaud's syndrome, (3) scleroderma.

I have never observed rheumatoid arthritis associated with arteriosclerotic occlusion or thromboangitis obliterans, and the joints of patients who have had their legs amputated for these diseases have, in my experience, shown no changes suggestive of rheumatoid arthritis. These observations are in accord with those of Hench, Kovacs and others.

Arthritis is uncommon in Raynaud's disease and in this condition no one can deny that the blood supply to the extremities is decreased. Indeed, one may see the most extensive changes in the skin and bones in this condition and no changes in the joints.

In scleroderma, the same condition is true. There are certain features of this disease, however, that are extremely confusing with rheumatoid arthritis especially in the early stages when the process may be acute and associated with swelling and edema of the periarticular tissues. At this stage the condition may be indistinguishable from rheumatoid arthritis and this is not surprising since the tissues involved are those of the skin and subcutaneous tissue. As the process advances and the sclerodactylia appear, there can be little doubt as to the nature of the process. Then the joints can be shown to be free of the process. This is true in spite of the presence of marked alterations in the bone. There is another feature of scleroderma that may be confused with rheumatoid arthritis and that is the presence of fibroid nodules about the joints. When these occur however calcium deposits take place (Kalklicht or Calcinosis circumscripta⁴⁰), and since this condition is not observed in the nodules of rheumatoid arthritis the differentiation can be made.

Another argument in support of the decreased blood supply to the joints is the behavior of the blood sugar tolerance curves on venous blood. Abnormalities in the blood sugar tolerance curve have been found in a certain number of patients with rheumatoid arthritis by some and not by others^{41, 42}. When the difference in the arterial and venous blood sugar curves is studied it has likewise been shown⁴³ that the high point in the curve increases above the normal level in spite of the fact that the amount of sugar in the blood returns to the fasting blood sugar level by the end of the third or fourth hour. This delayed removal of sugar from the blood has been taken to indicate a decreased blood supply to the tissues and joints. At best this

evidence is of an indirect sort and before one could accept it as being of etiologic importance, it would have to be shown to be present in all cases and not due to causes other than an interference with the blood supply to the joints. It is well known that the delayed removal of the blood sugar may be altered with the age of the individual, the state of nutrition, the amount of sugar ingested and the previous amount of available carbohydrate in the body. Moreover, it can be shown that the blood sugar tolerance curve may show delayed removal at one time and a normal removal at another^{44, 45} and this may be observed in normal individuals or patients with various diseases.

Until all of the above-mentioned factors are controlled it cannot be said that the delayed removal of sugar from the blood in patients with arthritis is an indication of a decreased blood supply to the joints or evidence of a disorder of carbohydrate metabolism.

DISTURBANCES IN THE SYMPATHETIC NERVOUS SYSTEM

In view of the presence of vasomotor disturbances in the extremities of some patients with rheumatoid arthritis, it has been claimed that their presence is of importance in etiology. In some, the vasomotor symptoms appear before the arthritis, in others they occur early in the course of the disease, and in another group late or not at all. The hands may even be warm and show no alteration in capillary flow. Just how these disturbances in function can bring about inflammatory changes in the synovial membrane has not been made clear. Since the vasomotor symptoms disappear after sympathectomy it has been assumed that these changes are of etiologic importance in the disease. From the reports in the literature⁴⁶ it is not clear just how the course of the arthritis has been altered by this procedure since they have not been followed long enough. Rowntree and Adson are conservative when they point out that one should be cautious in evaluating the results of sympathectomy as far as the arthritis is concerned until they are followed over a period of years. That one can cause the vasomotor symptoms to disappear following sympathectomy is not surprising. But before one can accept the vasomotor reactions as playing a partial rôle in causing the joint changes it would have to be shown that (1) all patients have these changes before the appearance of the arthritis, (2) vasomotor reactions are capable of producing inflammatory changes in the synovial membrane, (3) the arthritis can be completely arrested by sympathectomy. Moreover, it will be necessary to study a large group of controls, that is, patients with vasomotor disturbances in other diseases or without any evidence of organic disease.

From the evidence at hand it cannot be accepted that vasomotor disturbances are of decisive importance in the etiology of arthritis.

When they exist, they undoubtedly contribute to the symptomatology but in the present state of our knowledge, it would be premature to assume that these changes are responsible for the development of rheumatoid arthritis.

From what has been said about the eclectic theory, it cannot be claimed for the studies of the gastrointestinal tract, the peripheral vascular system, or the sympathetic nervous system that they have yet thrown any clear light on the essential nature of rheumatoid arthritis.

CONCLUSION

From the discussion of these three theories of the etiology of rheumatoid arthritis it may be taken that none of them are wholly satisfactory or conclusive. The question then must continue to remain in doubt. However, the recent advances in our knowledge of the anatomical and physiological changes that occur during the course of the disease have created fresh suggestions for thought and have improved our understanding of the condition. Gradually, the types of chronic arthritis are being more clearly defined and there is emerging a better understanding of what one is dealing with when the subject is discussed. Progress is being made in this field in spite of the fact that it is slow.

Wide differences of opinion regarding etiology continue to exist and this state of affairs is desirable since it stimulates thought and investigation. Every effort should be made to determine the cause of chronic arthritis since it is only by knowing the etiology of a disease or its mode of inception that one can prevent its occurrence or control its progress.

DISCUSSION

THE CHAIRMAN To open the discussion I will call upon Dr. Walter Bauer who has been working on arthritis at the Massachusetts General Hospital and Dr. Keefer has been working on arthritis at the City Hospital.

DR. WALTER BAUER Judging from past experiences in medicine, it would seem right to conclude that the cause of a disease is unknown if there exists no unanimity of opinion in the medical profession as to its cause or treatment. If one were to go on this assumption in the case of rheumatoid arthritis he would be forced to conclude that it is a disease of unknown etiology. Dr. Keefer has not used this argument, yet he has arrived at the same conclusion. He has attempted to show that no one of the present theories pertaining to the cause of this disease has been proved beyond the point of doubt. The existing theories fall short because they are not based on sound facts or adequate proof has not been presented as yet.

One of our greatest needs in the study of chronic arthritis is critical appraisal of each newly proposed etiological theory as well as intelligent interpretation and evaluation of the supposed therapeutic benefits. Failure on the part of our profession to do so in the past is in part responsible for our present meagre understanding of rheumatoid arthritis. How much better for the profession and for the patients if we would only say we do not know the cause of this disease. Such an attitude would stimulate sound thinking and call for the study and treatment of each patient as an individual case. The end result would be a more nearly correct answer to the problem.

In order to evaluate correctly the theories and treatment of chronic arthritis one must not be content with labeling each patient arthritis. He should appreciate that there are many types and should therefore attempt to classify each patient as to the type of arthritis present. If this is not done, many cases of arthritis of known origin will be included under the heading of rheumatoid arthritis. Many of these cases run a self-limited course with eventual recovery. If they are incorrectly labeled and included under rheumatoid arthritis one will unconsciously be recording certain patients as cured cases of rheumatoid arthritis who in reality had suffered from gonorrheal arthritis or some other type of arthritis of known cause.

We have long considered degenerative or hypertrophic arthritis as primarily a degenerative disease. The word, arthritis when used in this connection is in a sense a misnomer because histological examination fails to reveal any important evidence of inflammation. We prefer the term degenerative type of joint disease because the primary change is one of degeneration of articular cartilage all other changes being secondary to this primary process. This type of joint change is demonstrable in some degree in all normal individuals with increasing age. This fact is not surprising if one recalls that articular cartilage is a relatively avascular structure with a limited ability to repair. Because of this limited ability of articular cartilage to repair one finds more evidence of changes resulting from the wear and tear of daily use and increasing age than in other tissues where each limitation of repair does not exist. One can readily demonstrate by careful laboratory and clinical studies that the greater the wear and tear unusual use and repeated trauma to which a joint is subjected the earlier these changes will appear. We farther believe that certain patients inherit poorer cartilage than others and in consequence develop the disease at an earlier age. For these and other reasons, we refuse to accept the various infectious, metabolic or endocrine theories proposed by certain workers. It represents a disease

of known origin which in many instances may represent nothing more than physiological aging. There may be certain accelerating factors which could conceivably injure or impair articular cartilage and thus allow for the early development of such joint changes. To date we have no proof of their existence.

I agree with almost everything that Dr. Keefer has said concerning rheumatoid arthritis. It is a chronic disease of unknown etiology, characterized by remissions and relapses. It is important to remember that such remissions may occur when least expected and may last months or years. Because of this fact, one must proceed with caution when interpreting the benefits derived from any form of therapy. It is equally as important to appreciate that a joint which has appeared clinically inactive for years will often show an active process without any evidence of healing when examined microscopically.

The joint pathology in rheumatoid arthritis is primarily one of inflammation and proliferation of the synovial membrane, all other changes being secondary. The pathological and clinical findings in these two diseases are in no way related. Therefore, there is little reason for confusing one with the other or for believing that they are both caused by the same etiological agent (unitarian theory).

If one carefully studies and follows a group of patients with rheumatoid arthritis for a long period, he finds it increasingly more difficult to obtain convincing evidence favoring either the focal infection, toxic, allergic or eclectic theory. Time will not permit presenting my reasons for making this statement.

I prefer to think of rheumatoid arthritis as a chronic infectious systemic disease of unknown origin, unrelated to focal infections. The organism responsible for the disease, its portal of entry, its length of residence in the body at any one time, the other pathological changes resulting because of its presence and many other factors are as yet unknown. There is considerable evidence in favor of its being a specific infectious disease, producing many other symptoms and signs than those referable to the skeletal system. However, time will not permit a consideration of all these points. Because of the chronicity of the disease, the persistence of systemic symptoms, the ever present evidence of infection, the proliferative joint lesions without evidence of repair, one might surmise that the responsible organism is quite different from the organisms causing the other types of infectious arthritis or any of the supposedly causative agents thus far isolated. What the organism is we do not know. Whether it is a virus or some other hitherto unrecognized organism remains for future work to disclose.

DR. HERBERT L. LOMBARD, Boston. Methods for the prevention of disease have been existent as long as the diseases themselves, according to medical history. Whether it was the propitiation of the gods, the devising of an ointment, or bowing to a taboo, there has always been some plan for disease prevention. In most cases, there was no scientific basis for the beliefs, although in the case of cinchona bark, quinine was found. Even as late as 1898 it was recommended to burn a village in Cuba to stop yellow fever, and most of us here can remember when each scale of the scarlet fever patient was considered a deadly menace. Other forms of misguided enthusiasm have resulted in various rules of hygiene. Too often physicians have urged the adoption of this or that method of living without any clear cut picture of its value. The sulphur and molasses days may have passed but who can be sure that many of the so-called principles of hygiene are properly named?

Rheumatism is the most frequently encountered

type of chronic disease. With 138,000 sick in Massachusetts, 6,000 completely disabled physically and twice that number economically, any method which could prevent this disease would be heralded by the entire profession. In order to obtain some information pointing toward the etiology of this disease, certain questions were incorporated in the chronic disease survey of 1929-1933. In this survey information was obtained from 75,000 individuals by means of house-to-house surveys. These individuals lived in fifty-one cities and towns of the State and, inasmuch as both well and sick were questioned, the information regarding the habits of living is pertinent.

No attempt was made to differentiate the various types of rheumatism and the findings are those of the disease as a whole, including hypertrophic arthritis and atrophic arthritis as well as individuals complaining of various chronic rheumatic pains. In any survey of this nature some errors are bound to occur. It is probable that some who claimed rheumatism as a disease were not so afflicted while others who maintained they were well may not have been so, but with an estimated error of not over ten per cent, the findings are of value.

The case records of all individuals were divided into two groups, those who had rheumatism and those who did not, and the habits of the two groups were studied.

Over one half of the individuals with rheumatism had had former attacks of rheumatic fever, frequent sore throats, growing pains, frequent colds, malaria, typhoid fever, diphtheria, and scarlet fever, while only slightly over one third of the well group had had these same diseases. This would point toward a greater susceptibility to rheumatism among individuals having had these diseases. In the rheumatism group 56.2 per cent were infrequent or non-users of the so-called protective foods, in the well group 41.6 per cent were non-users of protective foods. This points to a vitamin deficiency as a predisposing cause of the disease. Foci of infection were measured by poor teeth and tonsils. Here, again, the group with rheumatism had much higher rates than the well group, the rates of bad teeth being 53.8 and 32.5 per cent respectively, and bad tonsils 16.4 and 6.8 per cent.

Nervous temperament was another variable measure and an association was found between this condition and rheumatism. In the group with rheumatism lack of exercise was reported by 9.3 per cent of the patients and in the well group by 3.7 per cent. Overweight was reported by 30.0 per cent of the group with rheumatism and by 19.6 per cent of the well group. Chronic indigestion and the habitual use of laxatives were more frequent among the individuals with rheumatism than among the well, the chronic indigestion rates being 38.9 and 15.2 per cent respectively, and frequent use of laxatives being 40.5 and 21.8 per cent.

More individuals with rheumatism lived in damp houses than did well individuals. From the survey it would appear that the individual with rheumatism had had more attacks of certain acute illnesses, was an infrequent user of the protective foods, had or had had bad teeth and bad tonsils, had a nervous temperament, had insufficient exercise, was underweight, was constipated, and lived in a damp house. All this points toward better hygiene as a possible preventive of this disease.

The association of rheumatism with these variables does not prove causation. It is possible with some of the variables that the same cause which produced the variable also produced the rheumatism. For example, an hereditary influence might have made the individual susceptible to both bad tonsils

and rheumatism and the bad tonsils may not have been instrumental in causing the rheumatism. This reasoning however could not apply to nonusers of protective foods, and while these figures do not prove causation, they suggest possible predisposition. With personal hygiene as a possible preventive of rheu-

matism all individuals should acquire a knowledge of the subject and put it into practice.

(Dr. John P. Peters of New Haven, Conn., read his paper entitled "Some Factors in the Etiology of Bright's Disease.")

SOME FACTORS IN THE ETIOLOGY OF BRIGHT'S DISEASE*

BY JOHN P. PETERS, M.D.†

IT is possible to recognize clearly among the congeries of conditions that find their way into the category of nephritis a certain group of cases that originate in association with diseases caused by streptococci. The clearest example of these conditions is scarlatinal nephritis. Its exact relation to the antecedent infection is not clear. It is usually stated, not quite accurately, that it occurs after the initial disease has subsided. More precisely, nephritis manifests itself in the second, third or fourth week after the onset of scarlatina. At this time toxic manifestations of the infection have ceased and there is presumably an excess of antitoxin in the blood. This is one reason for believing that the scarlatinal toxins are not responsible for the renal disorder. Another is the fact that persons who have had scarlet fever and are therefore immune to the disease may, nevertheless become infected with the scarlatinal streptococcus and develop a typical nephritis. The organisms have been identified in the throats of some such patients. Lyttle¹ has found that formed elements increase in the urine of most patients with scarlet fever at about the time when nephritis usually appears. This would almost suggest that the nephritis is only an exaggeration of a phenomenon which is part of the normal course of scarlet fever. Additional factors, however, appear to be required to evoke such a major explosion. There is much to indicate that one of these factors is the presence of a residual infection. By this I do not mean a recondite focus, but an active septic process of some kind. The idea that nephritis is a remote sequel of scarlet fever is not supported by the analysis of a large series of cases in our clinic. It does not usually attack those patients who have an uncomplicated convalescence, but those who have a septic complication, such as cervical adenitis, sinusitis, otitis media, bronchopneumonia, etc., from which streptococci can be recovered. A similar point of view has been expressed by Longcope.² If the infection clears rapidly, the nephritis seems to resolve completely, leaving no demonstrable residue. In a certain proportion of cases, however, it becomes chronic. In all but the most fulminating of these it runs an irreg-

ular course, punctuated by exacerbations and remissions. These again appear to be precipitated by infections (usually respiratory) of the kind generally attributed to streptococci, and during these more active phases, in Longcope's² experience and our own, pathogenic streptococci can be recovered from the nose or throat with great frequency.

All that has been said of scarlatinal nephritis holds equally well for the nephritis that follows tonsillitis. There is the same interval between the initial infection and the appearance of renal and vascular symptoms, with the latter the same evidences of residual or persistent infection are found. The pathogenesis or nature of the renal lesions and the mode of action of the infectious agents I shall not consider except to state that the nephritis is probably not due to direct infestation of the kidneys by the streptococci. Streptococci were not in Longcope's series or our own, recovered from the blood or urine of patients with simple nephritis.

The analogy between rheumatic heart disease and nephritis has long been obvious, but has, in recent years, received increasing attention. In epidemiological characteristics as in their apparent relation to streptococcal infections and their remittent or intermittent courses the two diseases are quite similar. There is much to suggest that the connection is more than analogous. Studies of autopsy material have yielded such conflicting reports that McCann³ has even suggested that there may be geographical differences in the clinical character of rheumatic infections. A disease with all the characteristics of glomerulonephritis is undoubtedly encountered in the course of rheumatic fever in certain subjects. If rheumatic heart disease and nephritis are due to the streptococcus, there is no reason to believe that these streptococci are specific. Both heart disease and nephritis may occur as sequelae of scarlet fever, which may also give rise to typical arthritis. The simultaneous occurrence of the two diseases in the same subject seems altogether too frequent to be attributed to mere coincidence. Some time ago, in an analysis of the nature of infections associated with the onset of acute nephritis among 141 patients in the New Haven Hospital, twenty-two were found to have associated conditions that might have been referable to

*Read at the Annual Meeting of the Massachusetts Medical Society, Section of Medicine, June 4, 1933.

†Peters, John P.—John Blade Ely Professor of Medicine, Yale University School of Medicine. For record and address of author see "This Week" issue, page 159.

the streptococcus Of these ten, or 10 per cent, had outspoken arthritis In fact arthritis ranked fourth in the list of presumable etiological factors, with only scarlet fever, tonsillitis and coryza leading it Since then, possibly because more assiduous search has been made for manifestations of rheumatic fever in nephritis, the relative incidence of rheumatic nephritis has further increased Undoubtedly a plausible case could be built up for the inclusion of glomerular nephritis among the rheumatic infections It is not, however, my intention to indulge my speculative vein to this extent It may not be entirely idle to point out that the existence of a valvular endocarditis is generally accepted as *prima facie* evidence of rheumatic infection even in the absence of any history of arthritis, while nephritis which is known to result from indistinguishable infections is declared rheumatic only if it is attended by frank arthritis or valvular heart disease

Whether a true nephritis can be provoked by infections referable to organisms other than the streptococcus is a question which I shall not attempt to discuss at length, because my chief interest today is not the bacteriological aspects of etiology Certainly these other infections play a far less important or frequent rôle than streptococcal infections In the same series of cases of acute nephritis cited above, pneumonia appears as the provoking cause twelve times It may be worth noting that in no instance did nephritis develop in conjunction with a simple lobar pneumonia Always it appeared with some subsequent complication, varying from otitis media to empyema, most frequently with non-resolving or necrotizing pneumonic processes Hemolytic streptococci were recovered in this stage of the disease twice from throat cultures, once from sputum, once from empyema fluid and once from an otitis media, although some of these patients had initial pneumococcus infections Of course no conclusions can be drawn from such studies, except possibly that significance cannot be attached to sporadic cultures However, since repeated cultures were not taken in all cases the possibility cannot be excluded that streptococci might have been recovered from a larger proportion At least these nephritides cannot be ascribed unquestioningly to the pneumococcus

An attempt has been made to incriminate the streptococcus further by means of various serologic tests and immunologic reactions with results quite as suggestive and inconclusive as those which have been secured in rheumatic fever Epidemiologic and climatologic investigations have shown a rough correlation between the distribution and incidence of streptococcus infections, rheumatic fever and glomerulonephritis They have, however, been less successful in nephritis than in these other diseases,

probably because nephritis occurs less frequently and also because it lacks definition. Statistics can be of no value unless there is certainty that they deal with homogeneous data. The term nephritis is used so loosely that in ordinary parlance it has almost lost significance

At this point the specific etiology of nephritis ends, with nothing more than tenuous threads of circumstantial evidence incriminating the streptococcus or particular streptococci in a certain group of cases and with the great mass of cases entirely unexplained For try as we will, it is impossible to secure satisfactory evidence of an initial or antecedent streptococcal infection, or indeed a precipitating infection of any kind, in a large proportion of nephritic cases. Failure in this respect may derive in part from the perfunctory way in which histories are obtained The frequency with which a positive etiology can be traced is directly related to the attention paid to details in the anamnesis The latent period between infection and the renal disorder must always be kept in mind Unless the persistent septic process was severe the layman fails to recognize any connection between the renal symptoms and a respiratory infection that occurred so much earlier If the nephritis develops insidiously, as it may, the connection appears still more remote

The problem might be solved if it could be proved that the "streptococcal" forms of the disease had any especial distinctive characteristics, clinical or pathological Numerous workers have claimed that there are such distinguishing features, which have thereupon almost invariably served as a basis for a new classification of the disease, but the fallacy of these claims becomes immediately apparent when any one (or better, two) attempts to fit clinical material into the various categories

In general there is a tendency among clinicians to draw distinctions on the basis of symptom-complexes or functional disturbances in the great mass of cases in which the onset of the disease has not been observed or has been so insidious as to escape attention and to assign these conditions to categories to which some etiological significance appears to be attached Roughly, four or five large classes which appear under a variety of names are recognized in every nomenclature

- 1 *Acute nephritis* Characterized by its mode of appearance and the presence of one or more of the following symptoms edema, high blood pressure, vascular lesions convulsions, albuminuria, cylindruria, hematuria
- 2 *Nephrosis* Characterized by edema, albuminuria, low serum proteins and lipemia, without hypertension, vascular lesions or renal insufficiency

- 3 *Chronic glomerulonephritis* Characterized by hypertension and its sequelae and vascular lesions, with frank evidences of renal insufficiency
- 4 *Nephrosclerosis or Arteriosclerosis* Characterized by hypertension and its sequelae without evidences of renal insufficiency
 - a) Benign or functional, without obvious anatomical arterial changes in the early stages.
 - b) Malignant, with obvious arterial lesions in the early stages

The first three of these syndromes are usually looked upon as infectious, the last is more generally ascribed to metabolic disorders or to the degenerative changes of senescence. Some objection may be raised to the inclusion among infectious processes of the nephrotic syndrome. Whether this condition can arise, as has been suggested, as an idiopathic metabolic disorder, an indistinguishable syndrome is encountered in the course of glomerulonephritis or as the result of amyloid disease. Among adults at least outside of pregnancy, these two conditions account for the great majority of cases and should receive first consideration.

The term glomerulonephritis, or in fact, nephritis, does scant justice to the disease it is intended to define and, like other misnomers in medicine, is a constant source of prejudice. It has tended to focus attention too much upon the renal lesion to the neglect of the general vascular system. Undoubtedly glomeruli are injured, but this injury appears to be part of a general vascular disorder which evinces itself especially in hypertension. Damage to the finer blood vessels can be demonstrated by simple methods only in the kidneys and the retina in the kidneys because it manifests itself in albuminuria and hematuria, in the retina because these vessels can there be visualized. Only by indirect methods and very imperfectly can injury to the general vasculature be estimated. Therefore the fact that glomerulonephritis may do its major damage to vessels outside of the kidney is not sufficiently recognized.

A young colored girl of fourteen in the summer of 1924 had a mild attack of scarlet fever. About October 9 she developed a cold and a few days later began to vomit. October 14 she complained of severe headache and abdominal pain and on the 16th was admitted to the Hartford Hospital in coma, having had several convulsions with hypertension and albuminuria. She was discharged after two months with a diagnosis of acute nephritis with hypertension and albuminuria persistent. Three months later when she was brought to the New Haven Hospital Dispensary her blood pressure was 195/110 her brachial and radial arteries seemed tense and thickened and were described as pulsating forcibly. The urine had a specific gravity of 1.009 and contained a moderate amount of albumin and occasional red blood cells. The blood non-protein nitrogen was 23 mg per cent, the phenol sulphophthalalein excretion 60 per cent. Three

months later that is eight months after the original acute nephritis, albuminuria and hypertension remained. She was not seen again until April 19 1925 after an interval of three years. She looked surprisingly well her urine was entirely clear her heart of normal size. Her blood pressure by the oscillatory method was estimated as 115/70. It could not be measured by the usual techniques because no pulsations could be seen or heard in either the brachial or radial arteries. In December of the same year when she was admitted to the New Haven Hospital for a cervical lymphadenitis the blood pressure in the legs was found to be normal the renal concentrating powers proved unimpaired the blood non-protein nitrogen was 17 mg per cent and the phenol sulphophthalalein excretion 85 per cent. There were minimal changes in the retinal vessels.

In this case an acute glomerulonephritis of the most typical kind, probably scarlatinal, seems to have left its most prominent marks not in the kidneys, but in the systemic vasculature, where it caused obliteration of the brachial arteries. Other cases could be cited in which a more characteristic picture of nephrosclerosis has developed in the course of a disease which appeared to originate with a streptococcal infection.

The frequency with which the picture of advanced glomerulonephritis or nephrosclerosis appears as a result of bilateral obstruction of the urinary tract with infection is too little recognized. Longcope⁴ has recently called timely attention to this point. Our own attention was forcibly turned in the same direction by certain experiences with toxemias of pregnancy. It is now generally recognized that hydronephrosis is a natural concomitant to pregnancy in a large proportion of women, perhaps one of the ill-referable to assumption of the erect position, from which, as usual, the female is the chief sufferer. With this mechanical obstruction, for such it must probably be considered, infectious agents which may gain access to the urinary tract either from above or below, are given a peculiar opportunity to establish themselves and to work irreparable damage. It has surprised us to learn how many toxemias originate from this condition. Sometimes it may lead to a precipitate eclampsia, more often having become established as a chronic condition in one pregnancy, and perhaps aggravated by subsequent pregnancies, it gradually leads to secondary contraction of the kidneys with ultimate production of the characteristic picture of chronic glomerulonephritis or, more frequently, advanced nephrosclerosis.

CASE 37453 aged thirty-three was admitted to the hospital July 10 1925 about six weeks before term. A year and a half earlier her first pregnancy had been terminated at six months because of a severe pyelitis. After a prolonged convalescence she was pronounced cured but during the present pregnancy had been treated in another city for B. coli pyelitis. She arrived in New Haven feeling well but with slight edema of the feet July 6. On the morning of July 10 she complained of some

abdominal pain with nausea, and vomited. At 4 30 P.M. she was found in coma, breathing stertorously, at 9 30 she began a series of convulsions in which she was admitted to the hospital. She was delivered of a stillborn child by low forceps six hours later. After delivery she passed into shock in which state she died after another twenty four hours. Her blood pressure on admission was 180/100, but fell sharply after delivery. Her temperature rose from 105 to 107.4° while she was in the hospital. Catheterized specimens of urine contained large amounts of albumin, occasional casts, many white blood cells, red blood cells and bacilli.

This is only one of a series of cases in which a typical eclamptic toxemia seemed to arise from a pyelitis in pregnancy. In this case it proved immediately fatal. In cases that survive, the disease takes on the features characteristic of the secondary contracted kidney, with hypertension and vascular phenomena usually predominating.

CASE 55527 was admitted to the hospital October 6, 1926, at the age of thirty-eight. October 5 she had been delivered at home of a 4.5 lb baby at term. One week earlier a trace of albumin had been found in her urine, but the blood pressure had been normal. October 6 at 3 P.M. she had a sudden convulsion followed by the passage of a large amount of urine, "enough to fill 3 bed pans." The blood pressure was found to be 230/160. At 7 P.M. after a second convulsion she was admitted to the hospital in a condition of shock. She recovered from this after appropriate treatment, the blood pressure rising again to over 200 mm. During a febrile convalescence, owing to dysuria, frequency of urination, pyuria and pyrexia, a diagnosis of cystitis was made. It was then learned that she had been treated for cystitis at an earlier date. She was discharged with persistent hypertension, but readmitted five months later, after a slight convulsion, still complaining of dysuria and, in addition, of headache, with a blood pressure of 220/135, nonprotein nitrogen 31 mg per cent, phenolsulphonphthalein excretion 70 per cent. Cystoscopy revealed bacilli and pus cells in the urine from the right ureter. After this she was seen at intervals, suffering from the same conditions, which steadily increased in severity until death, presumably from a cerebral vascular accident in 1933.

Such cases could be multiplied. In some, autopsies have been secured which have supported the clinical diagnosis of chronic pyelonephritis with secondarily contracted kidneys. The same sequence of events, usually without early explosive incidents, is seen when infection and obstruction occur in the absence of pregnancy in either male or female, and the onset may be so insidious as to obscure entirely the true cause of the condition.

CASE A 33549 male aged forty-one, was admitted to the hospital January 29, 1934 complaining of crampy pains in the right side of the abdomen. Five years earlier albuminuria had been discovered in the course of a life insurance examination, although he had no symptoms of any kind. Three years later, because of pain in his back and indigestion, he consulted a physician who found profuse albuminuria and a blood nonprotein nitrogen of 48 mg per cent. It was after this that he began to suffer from the abdominal cramps with increasing fre-

quency. After another year the nonprotein nitrogen had risen to 59 mg per cent and the blood pressure was found to be elevated. On admission his temperature was 101°, the blood pressure 160/98, the retinal vessels were sclerosed and the peripheral arteries thickened. The urine was of low specific gravity and contained a moderate amount of albumin, a few red blood cells and a few white blood cells. B cells were found in catheterized specimens. The blood nonprotein nitrogen was 58 mg per cent, the phenolsulphonphthalein excretion was 25 per cent. Cystoscopy and pyelograms revealed bilateral hydronephrosis, with strictures of both ureters, more marked in the left kidney, which was almost functionless, while the function of the right kidney was greatly reduced. The blood pressure rose rapidly to malignant heights, heart failure and other sequelae of hypertension appeared, and he died about a year later. Autopsy revealed bilateral secondarily contracted pyelonephritic kidneys and general arteriosclerosis.

In this case none of the symptoms of hydronephrosis or pyelitis appeared until, judging from urinary findings and blood nonprotein nitrogen, the condition had become advanced. It is possible, however, that a diagnosis could have been made when the albuminuria was first discovered. The end-result does not differ from that seen in the cases which began with pregnancy toxemias.

Experience with cases of this kind occurring in pregnancy has engendered a certain skepticism concerning the general attitude toward toxemias of pregnancy. Pregnancy, besides obstructing the urinary tract in these cases, appears only to accelerate or exaggerate a condition that is predetermined by the conjunction of infection and hydronephrosis. Perhaps it predisposes more particularly to convulsive explosions. In other types of toxemias it is possible to detect counterparts of renal and vascular diseases which are found in the non-pregnant. The term toxemia with its unproved implications stands as a bar to the proper understanding of these conditions. If our present views should prove correct, pregnancy toxemias offer a fruitful field for the study of the etiology of nephritis and hypertensive conditions.

It seems hardly necessary to say that pyuria and bacilluria are sufficiently rare in nephritis to arouse immediate suspicion of pyelonephritis. By the time hypertension and renal insufficiency have developed, morphological abnormalities of the urine may be negligible, irreparable damage has been done and attempts to relieve obstruction are futile or dangerous. Benefit can only come from early recognition of these conditions and expulsion of the conventional cavalier attitude toward pyelitis. There is sound reason for believing that infection of the urinary passages is rapidly self-terminative unless it originates from the parenchyma of the kidneys themselves or is nurtured by improper drainage. The persistence of infection should therefore be taken as an indication of one or other of these conditions. Such an attitude

might obviate the disasters that usually result from congenital malformations of the urinary tract, and especially anomalies of the female urethra which are so frequently the cause of renal infantilism or rickets.

The main purpose of this argument, however, is not to draw any moral lessons, but merely to point out that the clinical pictures and functional disturbances which are ascribed to particular etiological agents, and especially the vascular disorders associated with renal disease may result from a variety of causes. It is not altogether strange that this should be the case. The relation of hypertension to renal injury is quite mysterious. To call it a "compensatory reaction" may be comforting to those who find relief in calling names, but to a realist such a term can have no physiological significance. Even compensatory reactions can find expression only through existing physiological mechanisms. In streptococcus infections the changes in kidneys and arteries are, so far as we can discover, only responses of these tissues to some stimulus, whether this be toxic allergic or what not. Vascular responses, as yet indistinguishable, may be provoked by certain more direct injuries to the kidneys. Hypertension, however, is not an invariable sequel of renal destruction, no matter how far or how slowly this proceeds.

A young woman with destructive lesions of the kidneys due apparently to local infection with non-hemolytic streptococci was followed for eight years after signs of severe renal insufficiency had developed. For the last year the blood nonprotein nitrogen varied constantly about 100 mg. per cent. Nevertheless her blood pressure was never elevated and there were no signs of vascular disease elsewhere in the body. Perhaps for this reason she also remained free from the distressing symptoms which usually attend this degree of renal impairment.

It has been demonstrated that hypertension is part of the syndrome that results from hyperactivity of the adrenal cortex* or the basophilic cells of the pituitary gland*. Autopsies on cases with tumors of these tissues have revealed renal and arterial lesions that cannot as yet be distinguished from those of nephritis or arteriosclerosis. This has led some to conclude that hypertensive states of various kinds are caused by overactivity of these glands and, with this view, new therapeutic measures such as adrenal ectomy and irradiation of the pituitary have been advocated and employed, usually without benefit. Behind many of these efforts there seems to be the idea that these hypertensive states are expressions of primary disease of these endocrine organs, whose functions are still so ill-defined. Cushing* and Zimmerman* have demonstrated in the hypophyses of patients who have died of renal and vascular diseases with hypertension abnormal accumulations of baso-

philic cells. It will take far more extensive studies to establish any correlation between the basophilic proliferations and these vascular disorders. But if the association is established it will still be unjustifiable to ascribe to these basophilic cells a primary role in the etiology of the hypertension. Zimmerman's series of cases, with which I am most familiar, appears to be, from a clinical standpoint, most heterogeneous. Any statement concerning the relation of basophilism to hypertension is, at this time, mere speculation. With this clearly understood it is permissible to suggest that the diffuse basophilism described in hypertensive cases by Cushing and Zimmerman may represent only the intermediary physiological mechanism through which in certain diseases or in injuries of the kidney hypertension and its accompanying phenomena are actuated. And it may well prove that basophilism is not the only mechanism by which this is effected.

The term nephritis is still applied clinically to a wide variety of conditions. In the solution of the problem of etiology careful clinical observation and description cannot be set aside because bacteriology and endocrinology have offered new methods of approach. Even if streptococci or other organisms are responsible for the production of certain cases of nephritis it will still be necessary to find criteria by which these cases may be distinguished. Such differentiation has been retarded by the tendency to look on nephritis as a disease of the kidneys rather than as a general vascular disease. Although hypertension and its associated vascular lesions can apparently arise from primary diseases of the urinary system, renal lesions can equally well result from primary vascular disease. As yet pathology and the clinic have not found in the fully developed disease pictures the marks by which the initial sequence of events can be distinguished. Perhaps the difficulty lies in the fact that distinctions have been drawn on the basis of criteria which are not directly related to primary etiological agents, but are merely secondary responses of inherent physiological mechanisms which may be activated indifferently by a variety of agents or disorders. The pathogenesis of symptoms and signs is a valid and essential concern of those who are investigating more fundamental problems of primary etiology. It is a more immediate interest of the clinician who is still compelled to rely upon symptomatic therapy. This requires above all more accurate analysis of the course of disease in those cases in which a presumptive etiological factor can be found, without the traditional preconceptions which, though so strongly fixed in all our terminologies, are strangely of variance with ascertained clinical facts and with the modern discoveries of physiology and experimental pathology.

DISCUSSION

DR SOMA WEISS This presentation of Dr Peters' is of special interest because it deals with a new phase of knowledge of Bright's disease. Investigations of the past three decades have been busily engaged in classifications and in analysis of symptoms, signs and kidney function related to Bright's disease. Some of the most significant results of these activities consist in the separation of functional and structural renal changes of a primary inflammatory origin, on the one hand, and those due to primary degenerative vascular lesions, on the other hand. Among the vascular changes, those associated with arterial hypertension have become better understood. It is now established that primary arterial hypertension, regardless of its etiology, frequently results in progressive impairment of kidney structure and function, and contrariwise different types of primary lesions of the kidney and of the urinary tract lead to a secondary diffuse vascular response with arterial hypertension. Today, as was pointed out by Dr Peters, we recognize that the active lesions of glomerulonephritis do not require the presence of infection in the kidneys or other parts of the body. The tissue reactions in glomerulonephritis represent, apparently, an intrinsic response of the body frequently, but not always, set in action by an infection. The progressive changes in the kidney often proceed independently of the causative infection and may advance after eradication of the foci of infection. Indeed, examples are not lacking indicating that in the causation of inflammatory reactions of the kidney, infection is but one of the trigger mechanisms. Thus a closer study of the kidneys in the "malignant phase" of hypertension, so-called, reveals that inflammatory changes leading at times to acute necrosis may result from acute local anoxemia of renal vascular origin.

Today we have also a better understanding of the relation of congenital and acquired obstructive lesions of the urinary tract to the development of pyuria and pyelitis, so-called. The appreciation of the frequency and importance of these transient local renal infections in the precipitation of pyelonephritis and focal nephritis represents also a definite and significant advance. It is of special interest, and bears on the better understanding of the clinical course of a group of patients, that the inflammatory and vascular response of the kidneys to local infections may proceed long after the absence of bacteria, and the healing of the active local infection.

The relationship between pregnancy and kidney and vascular diseases, although far from being settled, is becoming better understood. As Dr Peters has implied in the light of present knowledge the term toxemia of pregnancy is rapidly becoming a misnomer, hindering the advancement of knowledge and the use of this term is comparable to

the incorrect use of psychosis of pregnancy, as a condition *sui generis*.

Pregnancy is apt to precipitate pyelitis and pyelonephritis, and may accentuate the vascular, renal and cerebral manifestations of a latent glomerulonephritis, or a primary hypertension and nephrosclerosis. The detailed mechanism responsible for such effects of pregnancy is by no means clear, but some of the operative factors are known. Thus it is established that mechanical pressure by the pregnant uterus on the ureters leads to stagnation of urine and to pyuria and pyelonephritis. Similarly, pressure on the renal veins in certain forms frustes lesions of the kidney is perhaps a factor in the precipitation of renal disturbances and arterial hypertension. Pressure on the splanchnic vascular system in pregnancy may be an active factor in the elevation of arterial pressure by interfering with one of the most important vasoregulatory mechanisms. In addition to these mechanical factors, changes in internal secretion, in metabolism and in immunological reaction of the body in pregnancy may bear on the apparently altered reactivity of the central nervous system to cardiovascular renal changes.

Now the appreciation of these recent contributions will be of great aid in the understanding of the clinical pictures as presented by the patient. One of the weighty arguments often used against the validity of the subclassifications of Bright's disease is the fact that many, if not the majority of cases, do not fall clearly in one or the other groups. It may be worth while to point out, on the other hand, that classifications in biological sciences simply imply the definition and description of existing principles. Classification does not rule out, on the contrary, it often implies the existence of a combination of clinical or morphological principles. It is essential to emphasize that a combination of the types of kidney changes described in various classifications is common. Thus if glomerulonephritis or pyelonephritis precipitates arterial hypertension, the effect of the latter on kidney structure and function will become important. Depending on the duration and severity of each of the two conditions, clinical and histological manifestations of one or the other condition will be predominant. Cases such as those described by Dr Peters, which start as pyelonephritis with hypertension, are also not rare, the pyelonephritis may then completely heal but the hypertension persists, and the ultimate predominant renal disturbance may be an advanced nephrosclerosis with evidence of old healed pyelonephritis.

If we remember, therefore, some of the points discussed by Dr Peters, it is to be expected that the clinical and laboratory findings, as well as the histological picture in Bright's disease, will show great variation from patient to patient, even in those with the same type of renal disease. The present tendency toward simplification by clinician and pathologist is often at the expense of the exact truth. On the other hand, on the basis of a good anamnesis and a careful study of the patient it is often possible to elicit the combination of factors active.

In spite of the pessimism of many, we have traveled a long distance since the time of Bright. By defining not only what we know but also what we do not know, as has been done here by Dr Peters, the way is paved for future progress for the foundation of new knowledge often depends on the crystallization of our ignorance.

I am certain that I express the sentiment of this gathering when I say we are greatly indebted to Dr Peters for his interesting and valuable discussion.

Dr. JAMES P. O'HARE, Boston Dr. Peters in the paper he just read has hit on several deficiencies in our knowledge of the etiology of this disorder we have come to call Bright's disease. The particular etiologic factors that he mentioned pyelonephritis and basophilic, numerically represent a rather small portion of the commonly accepted causes of the various forms of Bright's disease. His group of these is very much larger than is usually found in the literature. In our patients at the Brigham Hospital we have had but one case of rheumatic fever as the probable cause of the acute nephritis. With more careful histories we would no doubt find a larger number. The importance of Dr. Peters expressed facts lies not so much in these particular causes as in this, that he has exposed many fundamental weaknesses in our knowledge of the etiology of nephritis and has gone on farther to show us ways by which we can remedy those weaknesses.

To me the most important part of his message is the statement repeatedly made that nephritis is not a disease solely of the kidney. Bright's disease in any of its various forms is never a disease of the kidney alone. Once we get away from that idea, the better we will treat our patients. Let me call your attention to the importance of these extrarenal factors. In chronic glomerulonephritis practically one-third of our patients do not die from their renal disease, but from extrarenal factors before the kidneys become insufficient. In the larger group of chronic vascular nephritides two-thirds die from

cardiac disease or something outside the kidneys.

It is pertinent to repeat here the words of Woodruff. Some years ago he told us that in nephritis albumen occurred in the gallbladder as well as in the urine and if it were as easy to examine the secretion of the gallbladder as it is to test the urine we might be calling nephritis by some other name.

Dr. PETERS Dr. O'Hare seems to have misunderstood my statement concerning the frequency of rheumatism in nephritis. It occurred in 10 per cent of these cases which were associated with streptococcus infections, not in 10 per cent of the cases of nephritis. In this connection I might add that we have been struck also by the frequency with which rheumatism occurs in conjunction with toxemia of pregnancy. One case seems especially significant. A patient admitted to the hospital in coma died about twenty-four hours later. She had albuminuria and hypertension. But because she was known to have had chorea before her terminal illness she received a diagnosis of chorea not toxemia.

THE CHAIRMAN I am sure we are all grateful to Dr. Peters for coming up here and giving us such an excellent and instructive paper.

(Dr. Howard B. Sprague of Boston read his paper entitled "The Etiology of Degenerative Vascular Disease.")

THE ETIOLOGY OF DEGENERATIVE VASCULAR DISEASE*

BY HOWARD B. SPRAGUE, M.D.†

THE study of chronic disease in man must inevitably be difficult. By definition its development takes place over a long period of time and it is not until the anatomical changes have become largely irreversible, and profound enough to cause symptoms that it is possible to know of their presence. Especially is this true of degenerative vascular disease when it attacks the most important organs of the body, heart, brain, or kidney. No one investigator can expect to live long enough himself to observe the development of vascular disease in any considerable number of individuals. Again the location of blood vessels developing from mesodermal anlagen makes them difficult of access. The main channels of the vascular system, with the exception of those in the retina, are deep in the body, lying in the brain in the abdominal and thoracic cavities or in the muscular and supporting structures, and are not available for such easy study as are structures of ectodermal or endodermal origin.

The student, therefore, is forced to draw conclusions about the natural history of chronic blood vessel disease by observing the condition of the vessels in a cross section of human subjects of all ages by studying vessels which normally undergo rapid regressive changes such as

those of the placenta and ovarian follicles, or by an attempt to accelerate vascular degeneration in experimental animals. In the latter attempt he may be forced into incorrect deductions by the artificial conditions of the experiment. For example, Klotz (1908) was able to produce hypertension in the thoracic aorta with degenerative changes in rabbits by hanging them up by their hind feet but rabbits do not normally emulate monkeys by hanging in this fashion and certainly not for the prolonged periods of this experiment—three minutes a day for 130 days.

Another obvious difficulty has been the complexity of the pathology of the arterial and arteriolar tree. In spite of the possible difference of mechanism in the pathogenesis of medial and intimal lesions it has been so far impossible to divide them satisfactorily and it still remains most practical to group them under the heading of arteriosclerosis. The main types as Long¹ suggests, may be recognized as arteriolar sclerosis related to hypertension reparative thickenings following toxic and infectious injury and the senile changes of age. In other classifications the reactions of small arteries and arterioles are separated from those of the large arteries, but as Ophüls² says this merely makes the distinction between nodular and diffuse sclerosis. It seems at present beyond our power to differentiate clearly intimal and medial processes or to subdivide significantly hyaline,

†Sprague, Howard B.,—Assistant Physician, Massachusetts General Hospital. For record and address of author see "This Week Issue" page 659.

fatty, fibrous, and calcific changes from each other. The key apparently lies, as Wells³ suggests, in the mechanism of the aging of colloids and the behavior of elastic tissue.

It is obviously impossible to discuss in twenty minutes the causes of such a large and variable group of chronic progressive changes in blood vessels as those which come under the general heading of arteriosclerosis, but one can indicate the main lines of thought of the past and the present. This has recently been done in the survey of the Josiah Macy, Jr. Foundation in a book of over six hundred pages¹. To mention the factors held at different times to be responsible for degenerative vascular disease is to catalogue almost all of the environmental influences to which the human race and its lower ancestors have been exposed. In the main, however, we may divide them into groups, and consider vascular disease as having been thought to be due to the following: (1) material voluntarily ingested food and accessory food factors, drink and drugs, or the products of the combustion of tobacco or similar plants, (2) material involuntarily ingested, inhaled, or acquired parenterally bacteria, viruses and their products, poisons (such as lead or noxious gases), (3) toxic products endogenously elaborated in the body such as occur in metabolic disorders like diabetes, gout, and renal disease, (4) general strain on the vascular tree from hypertension or excessive bodily activity, or local strain on special vessels from their anatomical situation or structural peculiarities as in the pulmonary or coronary circulation, (5) an acceleration or exaggeration of the changes normally occurring in old age, chiefly dehydration, loss of muscle cells, elastic tissue and power of regeneration, the deposit of lipoids and calcium salts in the cells and the changes in the colloid state of the tissues, based on an inherited somatic inferiority of the vascular system peculiar to the individual, his family or his race (this view was upheld vigorously by Warthin), (6) endocrine influences through hypoadrenalism, hyperadrenalism or dysfunction, (7) the influence of psychic factors, worry, economic struggle, emotional strain, and the speed of modern life, upon vascular irritability, (8) climatic factors.

One sees in the alternate rise and fall of these various theories of the cause of degenerative vascular disease an, as yet, unavailing attempt to discover, as Cohn⁴ says, "to which category arteriosclerosis belongs—to remediable occurrences, or to the inevitabilities." Only great optimism can, at the present time, lead to a belief that arteriosclerosis can be deferred or prevented by any change in human environment. For every theory of etiology instances can be adduced for disproof and for every mechanism an uncontrolled variable in the experiment appears, yet certain factors grow more

insistent as investigation proceeds. A few may be mentioned.

(1) One of the most direct and repeated contacts that an organism has with its environment is through its food, and it is difficult to eliminate this factor from any alteration of the human body. As the Germans say "Mann ist was er isst"—man consists of what he eats. When a substance appears so commonly in a diseased artery as does cholesterol it seems obvious that there is some error in the utilization, or elimination, of cholesterol from the food or from the body stores, or some local cause for its deposition in the vessel wall. And in any discussion of experimental atherosclerosis the work of Ssolowjew and Amitschkow in Russia, Versé in Germany, and other investigators, with the production of atherosclerosis in rabbits by high cholesterol feeding must be given a major place. This work has been continued in Boston by Leary whose demonstration of coronary atherosclerosis and occlusion in rabbits has been dramatic. Objections have been raised to this work on the basis of the very large amounts of cholesterol administered, the fact that atherosclerosis is not a normal reaction of rabbits, and that the conditions are, therefore, highly artificial. In spite of these objections we cannot escape the fact that this demonstration is a most significant step in that atherosclerosis has actually been produced for our further study and in its production has shown some analogy with the arterial degeneration so strikingly frequent in diabetes in which disturbed cholesterol metabolism is a factor. Why it attacks specific areas of the vascular tree is yet to be determined.

So far as other foods than those containing cholesterol are concerned it becomes constantly less obvious that any can be convicted of causing vascular degeneration except the very high calcium diets in experimental animals. High protein diets are no longer attacked except by the red meat fearers and Katase⁶ has removed some of the misconceptions about acid-forming diets in showing that such diets when fed to rabbits produce tall slender animals while alkali-forming diets develop broad muscular animals. He called attention to the fact that in man the latter type are more prone to arteriosclerosis. Vitamine deficiency, especially that of vitamine C, may play a part in vascular disease and arteriosclerotics are said, by Weiss and Minot⁶, to feel better when fed a diet rich in complete proteins, vitamins and fruit. Total food intake is another problem. McCay and Crowell⁷ have recently shown that rats fed a balanced diet so low in calories as to retard growth and maturity have a measurably longer life than those on so-called optimal diets, which brings up the question of whether the nutritionist's ideal of high caloric diets causing rapid growth in childhood may not influence the susceptibility of the individual to degenerative disease in adult life.

(2) Tobacco has been a popular miscreant in the causation of vascular disease. This much can be said, that the modern work with skin temperature measurements by thermocouple has shown that smoking produces a rapid and measurable drop in skin temperature due to vasoconstriction. That this is harmful is not proved but peripheral vasoconstriction may be the primary mechanism of essential hypertension and it would also be undesirable in the coronary circuit. Like many of man's activities tobacco smoking is probably well tolerated by most of us but definitely harmful to some.

(3) Alcohol has lost much of the odium attached to it as a poison responsible for arterial destruction and there is even a tendency for opinion to swing to the opposite pole and of tribute relative freedom from arteriosclerosis to the ingestion of alcohol. This belief may be partly wishful thinking but, Leary³ has noted "the frequent absence of 'nodular' arteriosclerosis of the aorta among individuals who chronically drink alcohol." It seems fair to say that alcohol, of itself, does not produce arteriosclerosis but that excesses in other directions, as in overeating, may be promoted by the lack of judgment at times induced by alcohol.

(4) With regard to the influence of hypertension on vascular integrity we are still uncertain as to cause and effect. Experimentally hypertension from adrenalin produces arterial calcification in rabbits. However it has been quite well established that the fault in the system productive of high blood pressure in man is in the arterioles, the total caliber of which is reduced. The work of Weiss and his associates is showing that the vessel change is present very early but whether due first to vasoconstriction or intimal thickening has not yet been demonstrated. The reverse seems to be true when we study the effects on blood vessels due to increased local pressure or strain upon the walls. In the coronaries the position of the arteries, with their branches acting as fixed points in the muscle, leads to torsion and angulation which are considered elements in their degeneration and perhaps as determining the local deposits of cholesterolesters and other constituents of atheroma. In a similar fashion the effect of strain from hard work can be seen in the high degree of medial sclerosis and calcification seen in the arm and leg arteries of laborers and in Marchand's¹⁰ observation (cited by Bell) of a man of thirty five years who had poliomyelitis in childhood and showed marked calcification in the femoral artery of the normal leg but none in the artery of the paralyzed leg.

In the pulmonary circuit one is impressed with the frequent sclerosis secondary to increased blood pressure. Mitral stenosis with its

resulting pulmonic hypertension very often leads to vascular degenerations limited to the lesser circulation. We may be justified therefore in saying that essential hypertension derives from general arteriolar sclerosis whereas special examples exist which show that degenerative changes occur in larger arteries from localized increase in vascular tension.

(5) An appealing analogy between the normal atrophy of disuse of various organs and the processes of old age in the whole body was drawn by A. S. Warthin¹⁰ in 1929. According to him structures which are no longer of use to the individual such as the ductus arteriosus at birth, the placenta at term, and the ovary at the menopause undergo precisely the same regressive changes as does the whole body when it has lived its biological limit and fulfilled its function. Pathological or premature death from vascular disease or other degenerative process is, in his view, a matter of inferior germ plasma and like death from cancer is to be prevented only by a slow elimination of such germ plasma from the race by selective breeding.

(6) Much has been said in recent years about the influence of the acceleration of our present life and the strains of competitive existence in the production of disease of blood vessels especially of the coronaries. Critical analysis of the statistics as undertaken by Cohn and Lung¹¹ casts considerable doubt upon the existence of any marked increase in vascular disease. Many other factors enter into the interpretation of figures of mortality from heart disease, such as accuracy of diagnosis, fashions in diagnosis and the decrease of infectious disease not only in youth but in the decades in which a rise in circulatory diseases has taken place. Biological death, it must be remembered, is essentially vascular death and the more of us that live to attain this major involuntary period, the more of us will succumb to vascular pathology.

As regards the effect of the nervous competitive life in the production of arteriosclerosis a paradoxical situation might be mentioned. It has been shown that the African Negro in a state of nature is quite free from hypertension and arterial disease but on exposure to white civilization proceeds to become a victim to them. Hypertensive heart disease is the most frequent cardiac disease of the American Negro. If it is true that nervous strain is the cause of this, how can one explain on the same basis the freedom of the American Negro from angina pectoris, popularly attributed to nervous tension of modern life?

(7) Finally, it may be asked why arteriosclerosis in youth and middle age is so predominantly a male disease. We have recently analyzed the histories of twenty five patients, forty years of age or younger who had coronary

thrombosis Every one was a male No plausible theory seems obvious for this sex linkedness especially as more and more the lives of young men and young women are becoming similar in physical and emotional activity, work, play, and normal vices The answer to this question may lie in endocrine factors as yet undiscovered

SUMMARY

The cause of degenerative vascular disease is unknown but the boundaries of the problem are being progressively narrowed by the study of experimental arteriosclerosis, of chemical analysis of vessels, of the properties of colloidal gels, and of human biology No theory of etiology is wholly satisfactory to explain premature death from disease of blood vessels Acceleration of the normal changes of age seems to be inherent in certain familial or racial groups and can only be abolished by a wide, and probably impossible, application of human genetics However, enough evidence exists to make it probable that there are controllable factors of environment which, in some cases, can be altered in such ways as to delay the process of aging or change its manifestations

DISCUSSION

DR HENRY A CHRISTIAN Dr Sprague has presented to us a very excellent résumé of present-day knowledge of the etiology of degenerative vascular disease However, this must be sized up as a confession of ignorance, not on the part of Sprague but of medical science After account is taken of all past investigation we must confess that we know almost nothing definite as to the real cause of degenerative vascular disease

From time to time various causes have been assumed and, based on these assumptions, methods of prevention and of treatment have been applied Viewed with a critical mind it must be admitted that all of these methods have failed both in prevention and in cure Medical men have tried low protein diets salt free diets, alkaline ash diets, vitamin rich diets, cholesterol poor or fat poor diets, purin low diets, vegetable diets, fruit diets, semi starvation diets, sweats, purges, bleeding, heat and electrical currents, nitrites, nitrates, iodides, cyanates, liver extracts, these and more One by one all have been admitted by the most thoughtful clinicians to fail in their intent The lesson for the clinician from all of this is, be slow to accept and use therapeutic procedures as efficacious in the prevention or treatment of degenerative vascular disease and particularly be

slow when said method brings discomfort and debility to your patients We are justified today only in advising moderation in all aspects of life and in treating symptomatically, as best we can, disturbances as they appear in patients with degenerative vascular disease

In all the welter of ideas as to causes of degenerative vascular disease three things stand out prominently

1 Degenerative vascular disease most often is a manifestation of the aging process, the real why and wherefore we know not The quest of the fountain of youth still baffles Some individuals age prematurely as if they had been endowed with subnormal structures and particularly subnormal vascular systems Preventive and curative medicine alike are helpless when confronted with the problem of what to do with the aging process After all it is but physiological to grow old The late Charles Sedgwick Minot pointed out that senility began in embryo, meaning thereby that development of the normal fetus involved the degeneration of certain structures and throughout life such degenerations continued.

2 Heredity plays an important part in predetermining early degenerative vascular lesions Steadily we are spreading and deepening our knowledge of what determines heredity Human eugenics still remains the fanciful dream rather than the practical possibility of the lore of heredity Like the weather we can talk about its importance but we, as practical physicians, cannot do anything to influence it

3 Hypertension is associated with degenerative vascular disease in a large proportion of our patients Still we do not know the cause of hypertension We are ignorant whether at first it results primarily from peripheral vascular constriction of nervous origin or is due to primary disease of the arterioles We are not sure whether the degenerative lesions that appear in larger arteries in the train of hypertension result merely from the continued strain of high blood pressure or are due to whatever causes hypertension acting in turn first on arterioles and later on arteries Histological study of the arterioles in the high pressure regions of the body in patients with coarctation of the aorta in contrast to the study of similar vessels in low pressure areas in the same patient revealed no differences in structure, which is some argument against high pressure alone being an important primary causative factor in the vascular lesions of hypertension Certain it is that today we can accomplish very little in the treatment of hypertension so far as the primary condition is concerned

Notwithstanding our present manifest ignorance about the causes, prevention and treatment of degenerative vascular disease, we need not be entirely pessimistic as to future progress More undoubtedly can be learned of degenerative vascular disease It is probable that some remedial cause may be found and better therapeutic effects be obtained Essential vascular hypertension seems to me to be the type of degenerative vascular disease most likely to be clarified by further investigation and from such newer knowledge may come definite improvement in ways of prevention and methods of treatment.

DR R S PALMER Widespread vascular changes, especially in the minute blood vessels, associated with hypertension, have interested me especially It appears that hypertension hastens the aging of the vascular tree The final step in the mechanism of hypertension and indeed of the maintenance of normal blood pressure is the tone of these minute blood vessels The normal postural vascular tonus is a reflex, the afferent impulses of which come from all parts of the body, both peripheral sensory,

and visceral afferent nod meet the afferent side of the reflex arc in the hypothalamus, the afferent impulses going to the minute vessels by way of sympathetic fibers. The questions are: Why the unusual tonus of this reflex in hypertensives? Can the condition be controlled by interrupting this reflex arc by surgery on the sympathetic system? Or finally as I believe may not the solution lie in the higher centers, thalamic or cortical representations of the sympathetic nervous system? The problem may be one of conditioning of the so-called total response. The questions are easier to ask than to answer. Nevertheless attempts are being made in different places. At the Massachusetts General Hospital we have convinced ourselves that deoervation of adrenals, adrenalectomy, splanchnic nerve resection, x-ray of adrenals and pituitary are in fec

tive. We believe from our experience and that of others that extensive sympathetic resection or possibly anterior root section in certain selected relatively advanced cases may prove effective in staying the course of this disease.

In some cases we find psychogenic factors importantly related to sharp rises in the blood pressure and in a few of these simple psychotherapy has been a fairly successful therapeutic measure in a number of advanced cases symptomatic improvement has been very gratifying but with no marked change in the blood pressure.

(Dr Francis T Hunter read his paper entitled *Drug or Protein Allergy as a Cause of Agranulocytosis and Certain Types of Purpura*.)

DRUG OR PROTEIN ALLERGY AS A CAUSE OF AGRANULOCYTOSIS AND CERTAIN TYPES OF PURPURA*

BY FRANCIS T HUNTER, M.D.†

INTRODUCTION

AGRANULOCYTOSIS or agranulocytic ongia was first described by Schultz¹ in 1922. Since 1927 there has been marked increase of interest in the condition, as is shown by the curve of the number of papers published in each six months' period during these eight years (fig 1). Since the first suggestion that

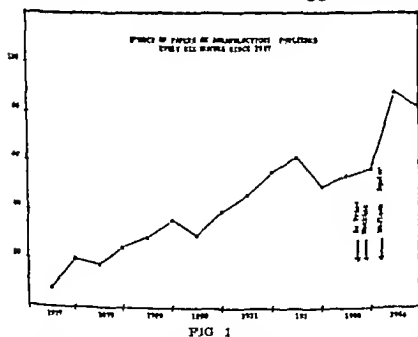

FIG 1

amidopyrine might be a causative factor this interest in the syndrome has become even keener. To De Vries² must go the credit of making the first observation in this respect. In September 1933, he reported a case of agranulocytosis with many recurrences. Five different attacks occurred, each time promptly after the ingestion of certain sedative drugs, most of which contained amidopyrine. One month later Madison and Squier³ read a paper on the same subject at Chicago, and in November a group of cases was published by Watkins⁴ of

the Mayo Clinic. The latter therefore, was the first in this country to call attention to the etiological importance of this class of drugs, as Madison and Squier's complete paper did not appear in print until March, 1934.⁴ From September 1933 to January 1935, twenty nine different papers on amidopyrine as a cause of agranulocytosis have been published.

The objects of this communication are to survey the world literature in respect to etiology, to outline the arguments for an allergic mechanism and those for the syndrome's being a manifestation of primary physiological liver injury, to collect the reported cases of agranulocytosis ascribed to amidopyrine to other drugs, and to other substances which seem to produce the same clinical picture, to inspect all cases to see if mention of allergy or of liver damage can be elicited from the case reports themselves, and to investigate what relationship, if any, drug and protein agranulocytosis bears to leukopenia associated with purpura and to leukopenia associated with purpura and anemia.

As far as can be learned, allergy as a cause of the condition was first suggested by Pepper⁵ in 1931. He noted allergy in the history of many of his patients and pointed out the relationship of leukopenia to Widal's hemoclastic liver function test. In the past few years several other authors have also suggested allergy as a cause, but without producing any clear-cut evidence to substantiate such a hypothesis. More recently there has been a growing suspicion among some investigators and clinicians that agranulocytosis and allied blood dyscrasias, following the ingestion of certain coal tar derivatives or the injection of protein or of drugs belonging to the orphenamine group, may be manifestations of an acute liver injury. There is only scattered indirect evidence in support of these hypotheses but the arguments

*Read at the Annual Meeting of the Massachusetts Medical Society Section of Medicine June 4, 1935.

†Hunter Francis T.—Assistant Physician Massachusetts General Hospital and Huntington Memorial Hospital. For record and address of author see "This Week's Issue" page 619.

which have been advanced for each are as follows

ARGUMENTS FOR ALLERGY

(1) There has not been found any constantly present organism to account for agranulocytosis, the blood-stream infection being in all probability, a terminal event. Harris and Schattenberg^{3, 4} claim to have demonstrated in guinea pigs the blood picture found in human cases by means of prepared toxins of *B. enteritidis* and *Streptococcus hemolyticus*. *Staphylococcus aureus* from a fatal human case brought about depression of the total leucocytes and neutropenia in guinea pigs, but failed to do so in rabbits. Fried and Dameshek⁵ claim to have produced agranulocytosis in rabbits by intravenous injections of *Salmonella supestifer*. Kracke⁶, however, points out that temporary neutropenia results from the intravenous injection of a wide variety of substances, such as milk, nonspecific proteins, dead and living bacteria and various types of inert, finely divided material. Similar experimentation has been pursued by Ricci⁷, who inoculated rats with living cultures of *Salmonella supestifer* and *B. pyocyaneus* and obtained varying degrees of leukopenia and agranulocytosis. His animals developed abscesses in the liver. Dennis⁸ placed cultures of *Staphylococcus aureus*, *Streptococcus hemolyticus*, *Streptococcus viridans* and *Proteus septicus* in parchment capsules, inserted these capsules in the abdominal cavity of rabbits and observed what he thought was agranulocytosis. A critical examination of his work leaves much to be desired. Most of the rabbits showed no drop but rather a rise in the total number of leucocytes, but some did show moderate to marked decrease of the polymuclear percentage. This was repeated by Meyer and Thewlis⁹ who were unable to confirm the work of Dennis with pyogenic bacteria. With *B. pyocyaneus*, however, they produced acute leukopenia in rabbits with death in forty hours, without decrease in the number of polymuclear cells. From this it would seem that the blood-stream infection is not the primary cause of agranulocytosis and that injection of the various organisms obtained from human cases has not satisfactorily reproduced the picture in animals.

(2) The observation that the "benzamine drugs"¹⁰ (amidopyrine, etc.) and the drugs containing metals (arsphenamine, the gold compounds, etc.) do not produce the syndrome except in certain individuals has been constantly made. This is so obviously true that it hardly needs comment. If it were not true, everyone who took a sufficient amount of these compounds would develop agranulocytosis. This manifes-

tation, then, is not a true drug poisoning, but an injury, possibly allergic-like, occurring only in certain predisposed individuals.

(3) The frequently observed sudden onset of agranulocytosis with chills, rigors and fever is similar to that which follows foreign protein injection. This is a phenomenon too well known to deserve prolonged discussion. The not uncommon occurrence of the same train of symptoms following blood transfusion is, in all probability, due to the transfer of minute amounts of foreign protein contained in the donor's serum. These symptoms are at times accompanied by leukopenia, and the whole disturbance may be markedly diminished in frequency, as Price¹¹ has shown, by insisting upon fasting blood donors. It must be pointed out, in all fairness, that a similar abrupt onset occurs in many acute infections due to specific organisms, for example, lobar pneumonia. Some investigators have even suggested that this, too, is a manifestation of allergy, but the matter is possibly still open to question. The most one can say is that the violent onset of agranulocytosis and of certain specific infections is suggestive of, but has not been proved to be, an allergic mechanism.

(4) Neutropenia similar to agranulocytosis is seen constantly in acute allergic shock in animals, and has also been observed in serum sickness in human beings. Because many authors, particularly those investigating problems of allergy, have noted this, it may be regarded as an established fact. Of the arguments in favor of the allergic nature of agranulocytosis this one seems to be of great significance.

(5) In a number of cases in which the agranulocytic syndrome occurred following the ingestion of certain drugs, after the patient was well, the signs and symptoms recurred upon ingestion of the same or similar drugs. This has been demonstrated for amidopyrine by Benjamin and Biederman¹², Corelli¹³, Costen¹⁴, De Vries¹⁵, Johnson¹⁶, Madison and Squier¹⁷ (two cases), Grant¹², Rawles¹⁸, Squier and Madison¹² (two cases), Zinberg et al.¹⁹, and Plum¹³. The last mentioned investigator administered 0.2 grams of amidopyrine by mouth to the patient reported by Knudsen²⁰, after the patient had fully recovered from the first attack. Total leucocyte and differential counts were made every half hour the first day, every hour the second day, four times on the third day and three times on the fourth day, and from then on once a day. All counts were doubly checked and the differential count was made on 400 cells. The patient, shortly after ingestion of the drug, developed chills and rigors, and a temperature of 40.1° C. The temperature returned to normal on the following day, but when it was at its highest point there was a positive

*Substances containing a benzol ring with an attached amine (NH_2). A comparative analysis of the chemical structure of this class of compounds has been made by Herz²¹.

urobilin reaction in the urine. The agranulocytosis in this experiment was not complete, but the immediate drop in the total number of leucocytes and the relative fall in the polymorphonuclear cell percentage was so striking that there seems to be no doubt of the causal relationship between the phenomenon seen in the blood and the ingestion of the drug (fig 2). The author

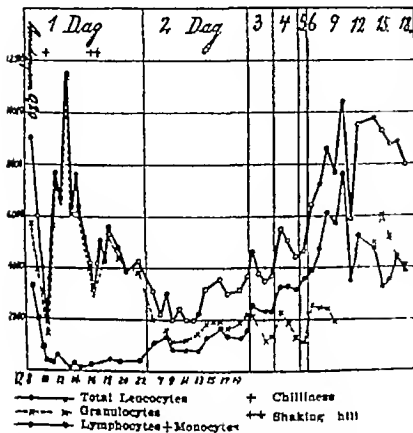

FIG. 2. Effect on white blood cells of Amidopyrine (0.1 gm.) in a patient who had recovered from agranulocytosis due to amidopyrine (Plim).

makes the comment that on the tenth day, when the monocytes and lymphocytes outnumbered the polymorphonuclear cells, the blood smear showed an appearance similar to that seen in infectious mononucleosis. A case of agranulocytosis occurring after the ingestion of amidopyrine and injections of vaccine has been reported by Andersen¹⁰². He noted a neutropenia in his patient on two later occasions, each instance occurring after the use of amidopyrine without vaccine. In the first recurrence twenty-five tablets of the drug were taken over a period of six weeks and in the second, twenty-five tablets over a period of sixteen days. It would appear that in this case the vaccine played no part in the causation of the first attack since amidopyrine alone produced the second and third.

The long lapse of time frequently seen between the commencement of drug ingestion and the onset of symptoms might raise doubts as to the etiological importance of amidopyrine, but it must be remarked that similar conditions may be seen in generally admitted cases of arsenic poisoning. The latter, however, is widely thought to be due to an idiosyncrasy to the drug, or in other words, drug allergy; therefore, in view of the careful observations of

Plim, and the scattered reports in the literature of recurrence of agranulocytosis after ingestion of amidopyrine, the only possible explanation of these findings is that of drug allergy.

(6) It has not been demonstrated that drugs of the aliphatic series (straight chain carbon compounds containing no benzol rings) can produce clinical agranulocytosis. A special report of the Council on Pharmacy and Chemistry of the American Medical Association¹⁴, June 1934, stated that up to that time no definite case of agranulocytosis had been reported in which harital alone (a straight chain compound) was responsible. There are no cases in the literature from the Council's report until January 1935 which deny this statement, and since straight chain carbon proteins, such as gelatin, do not produce allergy when injected into animals, these facts may be regarded as further evidence that the mechanism of agranulocytosis, from either drugs or protein, is in all probability an allergic one.

(7) There seems to be a close relationship between certain of the blood dyscrasias due to drugs. Varying in degree of severity from slight leukopenia to aplastic anemia they appear at first sight to be different clinical syndromes. But, that the same drug may produce purpura in one individual, in another agranulocytosis, and in a third agranulocytic purpura argues for a mechanism common to all. At times in these cases there is a history of former intolerance to the drug, such as nausea, vomiting, fever, dermatitis, or mild anemia. This has been noted by Alexandrescu-Dersca et al¹¹⁵, Carnot et al¹¹⁶, Farley¹¹⁷, Plá and Bennat¹¹⁸, and Rodriguez¹¹⁹. McCarthy and Wilson¹²⁰ reported a case of thrombopenic purpura following arsenic amine. After recovery from the first attack, the patient again received a small amount of the drug (0.1 gram). At the end of a half hour there was a slight chill with immediate development of purpura and bleeding of the gums. Observations such as these clearly point out that certain individuals are, or can be made, remarkably susceptible to certain drugs, and therefore they must be considered in a state of allergy toward them.

(8) Agranulocytosis has been noted after injections of foreign protein, such as vaccines, serum, and malaria. Bromberg and Murphy¹⁰¹ for instance, reported a fatal outcome in a patient who had had bronchitis and asthma ten years prior to hyperthyroidism for twenty years and who did not tolerate thyroid substance. This patient received an injection of typhoid vaccine and six hours later developed malaise and fever lasting two days. A second injection was given and a few days later a low grade fever was noted. The fever soon became continuous and by the fourth day sore throat and jaundice had developed. On the ninth day

after the second injection of vaccine the total leucocyte count was 7,000 and no polynuclear cells could be found in the fixed preparation. Kracke¹⁰⁵ also reported a case in which the patient received various vaccines over a ten-year period. She had taken large amounts of coal tar derivatives for three years and showed definite methemoglobinemia. Four weeks prior to the first attack of agranulocytosis she completed a course consisting of five injections of typhoid vaccine. Soon thereafter the temperature rose to 103° F and the fever persisted in a milder form for the next four weeks. At the end of this period agranulocytosis with a total leucocyte count of 900 and complete absence of polynuclear cells was noted. She recovered from this and a subsequent one, but died in a third attack. There was no evidence in Kracke's report that vaccine was given between the attacks.

Reed¹⁰⁷ observed agranulocytosis with recovery in a girl of twelve. The child developed tetanus from a small wound and was treated intensively with antitetanic serum, both intramuscularly and intraspinaly, a total of 185,000 units being given over a nine-day period. On the tenth day serum sickness developed accompanied by an urticarial rash. As the symptoms gradually subsided, the patient steadily improved until the twenty-first day, when the temperature suddenly rose. Investigation showed the presence of agranulocytosis. Whether the serum was solely responsible is impossible to say as, because of convulsions, sodium luminal and avertin had been used in considerable amounts.

Jacobson and Abel¹⁰⁴ described agranulocytosis in two patients while undergoing malarial therapy for neurosyphilis. With the administration of quinine the blood returned to normal and the patients recovered. Meyer¹⁰⁸ also reported two cases following malarial therapy, but one of these must be omitted as a case of malarial agranulocytosis as the patient was at the same time receiving arsenic.

If one is willing to accept the examples given here as cases of agranulocytosis, and there was nothing in the protocols inconsistent with the diagnosis, the conclusion is justified that the syndrome occurs on rare occasions after foreign protein injections and is a manifestation of allergy.

(9) The drugs which have been implicated in the causation of agranulocytosis, namely the amidopyrine group* and the arsphenamines, at times produce skin eruptions without changes in the blood picture. These skin eruptions frequently itch or may be scarlatiniform. Culley et al¹⁵ observed a patient with a past history of jaundice, who, after his second injection of neoarsphenamine, had a chill followed by en-

largement of the lymph glands and a scarlatina rash on the body. Taussig¹⁶ reported the case of a patient who developed urticaria, angioneurotic edema of the lips, and bronchial asthma on two different occasions immediately after taking a five-grain tablet of amidopyrine. Meredith¹⁷ published observations upon a woman who on two occasions took allonal and immediately afterward developed itching lesions on the neck and thighs. Curiously enough, pure amidopyrine, when used, did not produce this disturbance. Hansen¹⁸ observed a twenty-year-old woman who had jaundice from neoarsphenamine, and after recovery, took one tablet of a drug containing amidopyrine. Five hours later she developed chills, itching and a generalized exanthem. Recovery took place within two days. Later the patient took one tablet of a similar drug and the phenomenon repeated itself. Crohn¹⁹ reported urticaria and angioneurotic edema in himself on three different occasions following the ingestion of drugs containing phenacetine. Unger²⁰ observed a patient with hay fever who developed urticaria and angioneurotic edema the day after taking three allonal tablets. Twelve days later the same phenomenon appeared after taking six grains of amidopyrine.

Skin eruptions from arsphenamine have been universally recognized for many years. A detailed discussion of this subject would add nothing new. In certain individuals sensitivity to the drug, with allergic-like skin manifestations, appears to have been demonstrated not only for arsphenamine but for the amidopyrine group as well, this makes it quite likely, therefore, that the development of agranulocytosis from these drugs belongs in the category of allergic phenomena.

(10) Agranulocytosis has been observed rather frequently in patients known to be allergic. Kopelowitz²¹ reported a case of agranulocytosis in a woman who had had giant urticaria fifteen years previously and recently dermatitis apparently due to sea-food. The patient was studied in a hospital and was given unnamed sedatives. After going home she had a chill, followed by malaise, sore throat, and a temperature of 102° F. On the fifth day the leucocyte count was 5300 with no polynuclear cells, the blood examination in all other respects was normal. The patient died on the eighth day with jaundice. Fondé and Fondé²² reported a case of agranulocytosis, apparently unrelated to drug ingestion, in a patient who had sensitivity to eggs. Each parent was known to be allergic. Fitz-Hugh²³ has recently restudied twenty-six of his cases and was able to state that six of the twenty-six had a history of allergy, three having migraine associated with urticaria, eczema or vasomotor rhinitis, one with asthma and two with food sensitivity. Whether these six developed agranulocytosis

*For a list of proprietary compounds containing amidopyrine see table 1.

after the ingestion of drugs could not be deduced from his paper.

Before amidopyrine had been suspected as an etiological factor in agranulocytosis Pepper noted four instances of the syndrome in allergic patients. The first had violent urticaria following a blood transfusion from a donor who had recently eaten a food to which the patient

is doubtful that arsphenamine and gold salts act as simple poisons and therefore it is more reasonable to suppose that all these reactions are allergic in nature.

ARGUMENTS FOR LIVER INJURY

(1) Leukopenia, sometimes accompanied by neutropenia, has been observed in a number of conditions in which it is known that the liver if not anatomically, is at least functionally damaged. Leukopenia occurs frequently in cirrhosis, it is a constant finding in typhoid fever with its focal liver necroses, it is a well known phenomenon in pneumonia occurring in chronic alcoholics, and it has been amply demonstrated in experimental anaphylaxis in dogs. Other examples will readily come to mind, but this type of argument, as is obvious, has no validity unless taken in conjunction with all other known facts bearing on the relationship of agranulocytosis to liver injury.

(2) There is a high incidence of jaundice in agranulocytosis, both in the idiopathic type and in that due to drugs, and is particularly frequent in the group caused by arsphenamine. Schultz's first five idiopathic (!) cases all showed icterus. In the last few years, however, an increasing number of cases without jaundice have been reported, so that at the present time a case incidence of 50 per cent would not be regarded as too high. In my own series of cases it occurred rarely and usually terminally. Even so, any clinical sign occurring in 50 per cent of the reported cases deserves more than passing interest, and it seems strange that jaundice has not led to more comment, speculation, or even investigation into the condition of the liver in this syndrome.

(3) Eosinophilia has been observed not only as a finding in certain forms of allergy but occasionally in patients with liver disease. In cases of agranulocytosis thrombopenic purpura, agranulocytic purpura and aplastic anemia following gold and arsphenamine therapy an 'eosinophilia of cure' has been noted by many authors, following gold therapy by Ameuille and Brailion²¹, Achard et al²², Brailion²³, and Chaband et al²⁴ following arsphenamine, by Andrews²⁵, Brants²⁶, Cassoute et al²⁷, Carnot et al²⁸ Esserfeld²⁹, Meyer³⁰, and Monquon and Fleury³¹. The significance of this is obscure since eosinophilia occurs in parasitic infestations, after splenectomy, and at times in cases of pernicious anemia inadequately treated with liver extract. It may, perhaps, indicate that the liver is not splitting foreign protein in a normal fashion.

(4) There is repeated reference to vacuolization of the liver cells, central necrosis or even early cirrhosis in some postmortem cases of agranulocytosis. Larsen³² and Rawles³³ observed liver changes in cases of agranulocytosis

TABLE 1

DRUGS CONTAINING AMIDOPYRINE

Afanal	Gynalgos
Allonal	Hexin

Geamin	Veropyrin

was sensitive. The total leucocyte count, which had been rising, fell back sharply. A second had hay fever and migraine attributed to food allergy. A third was proved food sensitive, a fourth had asthma, was sensitive to a number of foods and always exhibited an eosinophilia. This patient similarly to the first, developed urticaria after transfusion. In spite of these reports, however, a careful survey of the whole literature does not substantiate the claim that agranulocytosis occurs with great frequency in allergic individuals. This fact will be demonstrated later.

(11) Most observers admit that a high proportion of the reactions occurring during the course of arsphenamine or gold therapy such as dermatitis, jaundice, and disturbances of the blood occurs in the second course of treatment or after the second or third injection following a period of no treatment. Furthermore in three cases Emile Weil and Bousser³⁴ twice found in tridermal positive reactions to the salts of gold. They also claim that in cases of purpura due to arsphenamine, but not in cases of purpura resulting from gold therapy, specific precipitins can be found in the blood. These facts seem to indicate that a building up of sensitivity to this class of drugs may take place. If this is so it

sis from amidopyrine, Pellegrini⁸⁷ and Schultz and Jacobowitz²⁰, in cases ascribed to arsphenamine, Brailon⁹², in cases following gold therapy, Silver¹⁰¹, in a case due to dinitrophenol, and Mazet and Daumas¹²¹, in a case of aplastic anemia caused by arsphenamine. In the earlier literature prior to the suspicion that drugs were an etiological factor, similar postmortem hepatic changes were observed in idiopathic (?) agranulocytosis by various authors. Aubertin and Robert-Levy²⁷, Bacaloglu, Litarczek and Litarczek⁸, Benatt and Pfeuffer²⁰, Lande⁴⁰, and more recently by Winslow³¹. In sixteen autopsied cases reported by Lichtenstein³² liver changes of varying degree, ranging from vacuolization of the liver cells to central necrosis, were noted. In one of my patients who recovered from the agranulocytosis, but who suddenly died on the ninth day from rupture of the jugular vein, the liver showed evidence which strongly suggested a recently healed central necrosis. In none of the reported instances has there been any attempt to correlate the degree of liver damage with the stage of the disease in which the patient died. These lesions, moreover, are so frequently seen postmortem in a great variety of other conditions that they have no claims to specificity.

(5) Kracke and Parker³³ and Roberts and Kracke³⁴ have attempted to correlate the first appearance of agranulocytosis in 1922, its high incidence among individuals connected with the medical profession and among those of the laity in better economic circumstances, and its geographical distribution chiefly in Germany and the United States, with the commercial production and use of sedative drugs of the benzamine group. This has led to experimental attempts to reproduce the syndrome in animals. Kracke³⁵ claims to have obtained leukopenia and neutropenia with intravenous injections of hydroquinone and subcutaneous injections of orthoxybenzoic acid, and with sufficiently small parenteral doses of benzol in olive oil, he produced agranulocytosis without anemia or purpura. It is unfortunate that no studies of the liver were undertaken, for it is well known that drugs of the benzol group have a tendency to injure this organ. Jaundice or central necrosis of the liver is at times seen in chronic benzol poisoning (Hunter and Hanflig³⁶, Hamilton³⁷). Of the benzamine drugs, phenylhydrazin has been shown by Fiessinger and Laur³⁸ to produce vacuolization of the liver cells. That cinchophen at times produces acute yellow atrophy is generally accepted, and Quick³⁹ believes this to be an allergic phenomenon. Finally, a study of the protective effect of certain food substances in agranulocytosis may, in the future, throw some light on the problem, as Bonanno⁴⁰ has been able to produce agranulocytosis in guinea pigs by means of x-ray irradiation only in those animals placed

on an alkaline diet. It is possible that the diet used by him, besides being an alkaline one, failed to furnish a protective substance to the liver itself.

(6) Lastly, the argument is advanced that as the liver is known to be an important storehouse for hematopoietic maturation factors in pernicious anemia, it might be assumed that to it is delegated the function of manufacturing and storing maturing factors for the myeloblastic series as well and that this hypothetical function may be gravely disturbed or utterly destroyed without giving specific microscopical changes. This would accord with the theories advanced by Beck⁴¹, who feels that there are two factors in white cell development (a) a growth stimulating substance probably manufactured in the liver and not contained in commercial liver extract, and, (b) a chemotaxic factor which causes the neutrophils to be delivered into the blood stream. Custer⁴², while believing that "idiopathic" agranulocytosis can be differentiated from that produced by arsphenamine or sepsis by a careful study of the bone marrow, feels that the lack of a maturation factor in the "idiopathic" type is unique and that it therefore is a clinical entity. Should it be demonstrated in the future that the liver does contribute a maturing factor for the formation of leucocytes in the marrow, new fields for investigation would be opened up and possibly many conflicting opinions reconciled.

CASES IN THE LITERATURE

Turning now to the cases in the literature which have been reported under the term agranulocytosis due to various agents, there is obviously great laxity in the use of the term. Although it is believed by some (Kracke⁴³) that agranulocytosis, thrombopenic purpura, etc., are closely allied conditions, so much confusion has resulted from the grouping of these several syndromes under the one term agranulocytosis that, for the sake of clarity, it was found necessary in surveying the literature to reclassify the cases into the following four clinical groups: (a) *pure agranulocytosis* with leukopenia and neutropenia, the rest of the blood being relatively normal; (b) *agranulocytic purpura* in which neutropenia is associated with purpuric manifestations without anemia; (c) *pure thrombopenic purpura* unassociated with changes in the white or red blood cell picture; (d) *aplastic anemia*, in which all the formed elements of the blood are markedly depressed.

Table 2 shows all of the cases reported in the literature of pure agranulocytosis ascribed to drugs and foreign protein. It is to be noted that of the 139 cases ascribed to amidopyrine, only forty-one were detailed case reports, the rest were cases inadequately reported or merely mentioned. There were twenty-one clinical

†This patient relapsed with Amidopyrine alone.

cases of agranulocytosis without purpura or anemia following arsphenamine, many other cases have been reported but upon close inspection of the clinical evidence one is forced to place them in one of the other groups, either agranulocytic purpura, thrombopenic purpura or aplastic anemia. In addition to those tabulated there were twelve other papers reporting cases of agranulocytosis following arsphenamine therapy. These were published in foreign journals difficult to obtain. It was not believed worth while to undertake an investigation of them as it seemed fairly certain no new facts would have been brought to light, to this extent the bibliography and survey are incomplete.

In table 3 there is tabulated for the reported cases of drug and protein agranulocytosis the instances (a) in which an allergic history was noted (even including dubious phenomena such as arthritis and migraine), (b) in which a past history of liver injury was obtained, (c) in which relapse took place upon again receiving the drug, (d) in which the occurrence of clinical signs during the acute illness suggested an allergic mechanism or liver damage, and (e) in which changes in the liver were noted at

*This patient relapsed with Amidopyrine alone.

postmortem [The discrepancy between the totals in tables 2 and 3 is due to the fact that there were no positive instances in the cases due to antipyrin, phenacetin, amidopyrine and acetanilid, amidopyrine and arsphenamine vaccine and acetanilid, and malaria and arsphenamine, and they were therefore omitted in table 3] A similar tabulation has been carried out for my own series of twenty-seven cases of agranulocytosis, but of these amidopyrine could be considered as an etiological factor in only nine

A glance at the table shows that in the world literature a past history of allergy did not occur in any of the groups with notable frequency. The same holds true for a past history of liver injury. After the use of drugs, jaundice was observed only fourteen times, seven of which followed arsphenamine. In only fourteen cases was a relapse noted after taking drugs again. Fifty per cent of the skin eruptions occurred after arsphenamine, and seven out of eight instances of eosinophilia, after arsphenamine or gold salts. Evidence of liver pathology was scant (Lichtenstein's cases are not included here for they were not reported as cases of agranulocytosis due to drugs)

My own series likewise showed nothing striking. In the twenty-seven cases, of which sixteen are dead, I have tried to ascertain a past history of drugs or allergy in as many as could be reached. In twelve cases nothing is known in respect to either, ten of these patients are dead. In nine cases the onset occurred after the ingestion of amidopyrine, five of these patients are dead. Of the three allergic patients, one had migraine, a second had migraine associated with sensitivity to wheat, and the third had a past history of skin allergy in the form of recurrent urticaria (possibly due to food) and hypersensitivity to insect bites. This patient at postmortem showed extreme vacuolization of the liver cells, apparently similar to many other reported cases in the literature, but which, it must be emphasized again, is not a specific histological picture. Two cases followed protein injections. In one, the patient, who gave no history of allergy, had received vaccines for bronchitis. In the second, the patient had been given 1,000 units of diphtheria antitoxin with considerable reaction. About four weeks later a marked leukopenia and fever were discovered, but as there was relatively slight neutropenia it is doubtful whether this case should be included here, it has been, however, because for several months after recovery blood examinations revealed an eosinophilia of 14 per cent. Two cases of typical agranulocytosis occurred in which it is problematical whether drugs played any part in the etiology. In two other non-fatal cases the patients stoutly denied the use of drugs or injections of foreign protein. One of these patients is of interest because a year later she developed vasomotor rhinitis

Of the twenty-seven cases, therefore, there are only eleven instances which could by the greatest stretch of the imagination be said to have had any phenomena which remotely suggested either allergy or liver injury.

In table 3 are listed cases from the literature

TABLE 4

which have been carelessly called agranulocytosis. These fall into the three other classes mentioned above, agranulocytic-purpura, thrombopenic purpura and aplastic anemia. Of the cases of agranulocytic-purpura, one-half of the patients manifesting this syndrome after arsphenamine developed skin eruptions, in another instance occurring after the use of quinine and amidopyrine, there was a history of urticaria. In the thrombopenic-purpura group, two instances of jaundice occurred after arsphenamine, and in one there was a recurrence of purpura when the drug was again administered. Of the three patients with this syndrome following therapy with gold salts, one had a history of asthma. Among the cases of aplastic anemia due to arsphenamine or gold salts, jaundice occurred once after each drug. It can therefore be stated that to date there is no evidence in the literature that agranulocytosis and the allied blood disorders following the use of benzamine drugs or the injection of foreign protein occur more frequently in the frankly allergic individual than in the normal. The one significant fact which points to these four blood dyscrasias as being closely allied is that arsphenamine can clinically produce all of them.

SUMMARY

- (1) The world literature from 1927 to 1935 in regard to the causation of agranulocytosis by drugs and foreign protein has been carefully surveyed.
- (2) The arguments that the syndrome is a manifestation of allergy, and those which have been advanced to show that it is a result of primary injury to the liver, have been outlined.
- (3) Agranulocytosis occurs in susceptible individuals following the ingestion of amidopyrine, but in less than 10 per cent of the

- reported cases has this drug been proved, by further ingestion tests, to be the causative factor
- (4) Typical clinical agranulocytosis may result from injections of arsphenamine, gold salts, or foreign protein, or from the ingestion of dimethylphenol
- (5) Agranulocytic purpura has been reported as caused by arsphenamine and by quinine, thrombopenic purpura and aplastic anemia, by arsphenamine and by gold salts, but many of these cases have been incorrectly referred to as pure agranulocytosis (type Schultz)
- (6) In view of the difficulty of drawing sharp dividing lines between these various blood dyscrasias, and since arsphenamine can produce any of them, they may well be manifestations of a physiological mechanism similar to allergy, which, in turn may be dependent upon injury to the liver
- (7) There is not enough evidence in the literature or in the author's series of cases to state that injury to the blood forming organs from the use of drugs or foreign protein occurs more frequently in frankly allergic individuals than in normals, or often in patients with evidence of past liver injury than in those without it

CONCLUSIONS

Agranulocytosis is a syndrome rather than a clear-cut clinical entity of established etiology, and may be occasioned by a number of substances such as amidopyrine, arsphenamine, gold salt, dimethylphenol and foreign protein. It, together with some allied blood disorders, must probably be placed in the category of allergic phenomena, and may even be conditioned by functional damage to the liver

DISCUSSION

DR. HENRY N. PRATT: I want to make just one point in the discussion. You are all familiar with the five criteria which Dr. Rackemann has laid down for the diagnosis of the usually accepted allergic diseases. These are a family history of allergy, a presenting symptom which is an accepted allergic manifestation, a past personal history of some other allergic disease, positive skin test, and an eosinophilia. Such diseases are asthma, hay fever, urticaria, eczema, and some cases at least of migraine. Dr. Arter Coca refers to these diseases as atopic and sets them aside as a distinct group because heredity or an inherited tendency plays such an important part in them.

If we analyze Dr. Hunter's personal cases and those reported in the literature for the criteria of atopy we find first, the data on family history are inadequate; secondly the presenting symptom leucopenia is the point in question, thirdly omitting arthritis, which is a very questionable allergic mani-

festation, we find a past personal history of atopy in twenty-one of two hundred and eleven cases or ten per cent, a figure approximating closely the percentage of atopic diseases in the general population, fourthly ten cases or less than five per cent showed positive skin tests in spite of many trials to elicit the phenomenon, fifthly eosinophilia was only occasionally demonstrated. It seems reasonable to conclude therefore that agranulocytosis does not fall into the group of accepted allergic or atopic diseases.

But the term allergy has a wider implication. Literally it means altered reactivity. It implies an antigen-antibody reaction which has not been proved in all instances. Into this wider group of allergic diseases fall such phenomena as the tuberculin reaction, serum disease, drug eruptions, and industrial dermatoses. Such reactions are not dependent on an inherited tendency and are therefore not atopic. Skin tests may be positive by patch test in stead of scratch or intradermal. Eosinophilia is absent or less constant. It is in this wider group of non-atopic but allergic diseases that it seems reasonable to classify agranulocytosis, at least those cases where symptoms can be precipitated at will by administering the offending drug.

Finally the fact that the syndrome of agranulocytosis can be produced by several agents is a strong argument in favor of the allergic interpretation of the etiology for multiple sensitivity is characteristic of allergy.

DR. HENRY JACKSON, JR.: There is but little I can add to Dr. Hunter's very complete and excellent paper. I will make only one or two remarks.

In the first place I question seriously whether the extreme leukopenia secondary to arphenamine poisoning should be classed with true agranulocytosis. The peripheral blood picture differs notably in the two conditions and the histological changes in the bone marrow of arphenamine poisoning bear little resemblance to those seen in agranulocytosis.

In the second place I would emphasize strongly the necessity of adhering to certain rather sharply defined criteria of diagnosis when the etiology of a condition is under discussion. The term agranulocytosis has been loosely applied to a variety of pathological conditions some of which are but remotely connected with the true disease. The French hematologists, in particular, have been responsible for much confusion. We must define our disease before its etiology can be logically discussed.

In the third place few authors have given careful consideration to the actual temporal relation of the administration of the drug amidopyrine to the development of the clinical picture.

From my series of cases of pure agranulocytosis I have been able to find twenty-seven in which there was available unequivocal evidence as to the administration of amidopyrine and killed drugs. In seven of these the drug was taken in such quantities and in such relation to the development of symptoms that it must be considered as having caused the disease. In eight the drug was taken for varying periods and in varying amounts, but careful study shows that no causal relation whatever can be made out. For instance, one patient took amidopyrine consistently before each attack, but took still larger quantities during the height of the disease from which she eventually recovered. In another the patient took amidopyrine in considerable quantities prior to an attack, recovered and continued to use the drug without the slightest ill effect. In a third amidopyrine therapy preceded an attack, and was omitted thereafter yet the patient had two more equally severe attacks. In twelve

cases of the twenty seven no drug allied to amidopyrine was taken at any time. So far, therefore, as my own series is concerned, one may conclude that amidopyrine is of etiological importance in about one quarter of the cases.

Finally one hears the statement that the disease is rapidly disappearing and that this is to be attributed to the lessened use of the drug. Yet the fact remains that the sales of amidopyrine for the last six months of 1934 were approximately 28 per cent greater than for any other six months' period.

That amidopyrine is of etiological importance in a considerable proportion of the cases is not denied, but for the present, at least, it would appear wise to be cautious before stating that it is the sole or even the major cause.

DR HUNTER (closing discussion). In reply to Dr Pratt, I feel myself incompetent to discuss the type of allergic phenomenon which agranulocytosis might represent. I should like to see in the future more detailed histories in regard to allergy in patients who develop agranulocytosis. I do not feel that the negative evidence in the literature will necessarily remain true for all time.

I am glad that Dr Jackson has injected doubt into the discussion, because I am going to repeat that these cases of agranulocytosis after arsphenamine

were, so far as I could determine, typical cases with out anemia or purpuric manifestations. If we doubt these cases as being agranulocytosis, I can see no reason why we should not doubt all cases due to drugs reported in the literature. Whether the bone marrow in arsphenamine agranulocytosis differs histologically from so-called idiopathic agranulocytosis is not for me to say. I understand that the pathologists themselves are not as yet in full agreement on this point.

As a final remark I should like to call attention to the fact that the therapy of this condition has not helped us in the least in elucidating its etiology and, since doubts are in order, I propose to doubt the efficacy of nucleotide. Of the twenty seven cases in my series, twenty one were treated with nucleotide. Of these nine recovered and twelve died (57 per cent mortality), of the untreated cases two recovered and four died (67 per cent mortality)—a difference of mortality too insignificant to warrant confidence in the therapy. Furthermore, the reappearance of the polynuclear cells and the improvement on the fourth or fifth day which has been noted after nucleotide may also be seen in untreated cases and in drug ingestion tests, such as that reported by Plum.

(Meeting adjourned at 5 45 P M)

ELECTROSURGICAL CHOLECYSTECTOMY*

II Clinical Application

BY LESTER R. WHITAKER, M D †

EXPERIMENTAL results with the high-frequency electric current for cholecystectomy¹ have indicated that it is valuable in the treatment of the markedly inflamed, or sclerotic gall-bladder, the chief advantage being better control of hemorrhage. Investigation also showed that certain types of current should not be used alone for this purpose. Both the tissue-dissolving or so called "cutting current" and the unterminal coagulating, or "desiccating" current produced too much tissue destruction and not enough coagulation to prevent postoperative hemorrhage. The preferable operative method (described below) leaves the section attached to the liver in place and obliterates it by coagulation. The *interterminal coagulating current* has proved to be the best for this purpose. In the work here presented both fulguration² (spark-ing), and contact coagulation with a needle electrode were used. Thorek of Chicago³, as a result of his experimentation, came to the conclusion that only slow electrocoagulation to considerable depth by contact of a flat electrode should be used, and not the intense heat and superficial charring of fulguration. Since Thorek produces a firm coagulum which effectively controls hemorrhage, and at the same time thoroughly destroys the section of the gall-blad-

der left in place by this method, such an application of the current seems preferable.

A brief description of the operation follows. The viscera are packed away and retractors placed, the gall-bladder is aspirated and split longitudinally to the cystic duct, or near it, with "cutting current", high dehydration. Fluid and stones are removed by the aspirator and a spoon. Then by the same means the tissue of the gall-bladder is cut away at about a centimeter from its attachment to the liver. The bleeding vessels are tied. To avoid serious hemorrhage the section of gall-bladder adherent to the liver is not removed. This tissue is thoroughly coagulated and dehydrated by fulguration. If any considerable portion of mucosa is left it may regenerate, resulting in a persistent sinus. If the cystic duct can be readily located it is tied or drained as indicated, if not it is ignored. The region is well drained. Omentum is packed in to protect other viscera and prevent crippling adhesions⁴.

Thorek has employed this procedure with unselected cases of gall-bladder disease. Results in this laboratory and clinic, however, indicate that it should be confined to those cases where careful preliminary studies, including cholecystograms, show that the gall-bladder is considerably inflamed or thickened. Previous experimental attempts upon the non-sclerotic gall-bladder have not been so satisfactory as with the markedly inflamed or sclerotic gall-bladder and it seems that cases for this method should be carefully selected.

Aided by a grant from the Committee for Scientific Research of the American Medical Association.

†Whitaker, Lester R.—First Assistant Visiting Surgeon, Massachusetts Memorial Hospitals. For record and address of author see "This Week's Issue" page 639.

The first operation with the high frequency current was performed before the method just described was perfected on animals. From this patient, the gall bladder, which was moderately sclerotic, was removed by dissection from above downward. The "outting current" with low voltage, moderate dehydration was used, keeping close to the gall bladder itself, even in places cutting through its wall rather than to risk damaging adherent viscera. As the cystic duct was approached the cutting with the electric current was discontinued for fear of injury to an adjacent bile duct or hepatic artery. Only a few vessels had to be clamped and tied during this process. A little more blunt dissection isolated the cystic duct, which was tied. The gall bladder fossa was drained with cigarette drains without exposure of gauze. The patient made an excellent recovery. After experimental development of the method described, however it was considered so much safer that actual dissection of the gall bladder with the "cutting current" was never again attempted.

The new method was an outgrowth of that of Pribram's "mukoklase" which consisted in tying the duct, splitting the gall bladder, charring the mucosa with the actual cautery sewing the leaves of the vesicle together, and closing the abdomen without drainage. Pribram obtained excellent clinical results, but experimentally with the actual cautery we had post-operative sloughing and hemorrhage. It seemed preferable to remove redundant tissue of the gall bladder and electrocoagulate the remainder.

The first patient in whom the new operation was tried was a physician, an old personal friend. The diagnosis of chronic and acute cholecystitis with probable empyema had been made. The patient understood the condition, and since it appeared from animal experimentation that the new procedure would not only be allowable but probably would be the best adapted to his particular case, he agreed to its use.

Since the sixteen cases, in which electrosurgical cholecystectomy was performed, were selected, and since all furnish points of interest for discussion, brief histories, with comment, are presented.

Case 1 (Hosp. No. 224884) Operation September 28, 1931. The gall bladder was freed from numerous adhesions by blunt dissection then about two ounces of purulent material were withdrawn by aspiration. The inflamed gall bladder was treated in general according to the method described above.

In this particular case the cystic duct was not easily outlined on account of much inflammatory swelling of the whole region. The duct was left open a soft rubber tube being stitched to its cut edge. Cigarette drains with no gauze exposed were placed. The patient made a rapid and excellent recovery. The bowels began to move on the second postoperative day indicating practically no general disturbance of the peritoneal cavity. There were no signs of infection. Bile drainage stopped after a

few days and the sinus closed in due time. After three years the patient was in good health. He had had no symptoms referable to the biliary or gastrointestinal systems.

Case 2 Operation January 11, 1932. The gall bladder was so markedly thickened and firmly attached to the liver that sharp dissection was difficult and dangerous. It was split to the cystic duct with the cutting current and trimmed off about a centimeter from the liver all the way around. The cystic duct was so embedded in adhesions that no attempt was made to tie it. The fulgurated gall bladder tissue left attached to the liver was folded over with a suture. Two Penrose drains showing no gauze were placed in the kidney pouch running through the gall bladder fossa.

The patient made an easy recovery. She began to pass gas two days after operation. There was a profuse bile drainage for thirteen days. She was discharged on the twenty-fifth day. Two years afterwards she was in excellent health.

Comment. If the cystic duct is not tied, it is preferable to attach a soft tube at or near the stump rather than to depend on Penrose drains. It is not apparent that drainage delayed recovery in this case, and where the cystic duct can not be dissected free and securely tied drainage is imperative.

Case 3 Operation March 26, 1932. The gall bladder was tremendously thickened and fibrotic with pronounced adhesions, and rather small and shortened. It was split down the front with the cutting current. At the lower end the tissues were tremendously thickened with an angulated mass which the operator believed to be the common bile duct and which might have been easily damaged in dissection. Anterior angulation of the common bile duct to a pronounced degree has been noted in several cases where the gall bladder was shrunken and fibrotic. Apparently it was pulled up in the process of shrinkage. Redundant portions of the vesicle were trimmed away and the remaining section thoroughly coagulated. It was unsafe to dissect the cystic duct, so this was split a short distance and since it was not known whether the common duct also had been cut in this process the cystic duct was sewn together over a catheter which was left in it and brought to the outside. On account of the anomalous condition of the ducts and the tremendous inflammatory thickening about them the common duct could not be adequately palpated or explored with the probe. The patient however had never been jaundiced.

Bile drainage was profuse from the first day. Five days after the operation the patient developed scarlet fever. There was tremendous infection with sloughing of the drainage tract which remained open for three months. About a month after it closed the patient had an attack resembling biliary colic, followed by jaundice with reopening of the sinus. Injection of iodized oil under the fluoroscope (followed by radiogram) at this time showed a filling defect at the lower end of the common bile duct indicating a stone. Incidentally the whole biliary tract was injected and the patient suffered no reaction. Even though the stone was not removed the sinus tract has now closed. The patient will probably have a recurrence of the jaundice from blockage of the common duct by the stone.

Comment. This was a suitable case for electrosurgical cholecystectomy on account of the tremendous thickening of the gall bladder and

fibrous attachment to the liver. It illustrates angulation of the common duct by shrinking of the gall-bladder with the danger to the duct this carries at operation. Since the cystic duct could not be safely dissected free, drainage was imperative. The tube in the duct was preferable to flaccid drains as it minimized soiling of the local peritoneum. Before the patient contracted scarlet fever he was making a rapid recovery.

CASE 4 Operation May 10, 1932. Adhesions were so dense that the duodenum had to be cut away from the gall bladder with sharp dissection. The gall-bladder was small and contained mucopurulent material. The cystic duct was apparently closed by fibrosis. The viscus was split, the excess trimmed away, and the remainder coagulated. The stump of what appeared to be the cystic duct, though surrounded by much thickened tissue, was whipped over with fine chromic catgut stitches and two Penrose drains were placed near the stump.

The patient made a rather difficult recovery, having a good deal of distention, but no severe complications. There was moderate discharge of bile which began nine days after the operation and continued for three weeks. The patient left the hospital in good condition after four weeks.

Comment. This was an ideal case for electro-surgical cholecystectomy. Since the cystic duct apparently was not securely closed, drainage was probably a life-saving procedure. On the other hand, one might consider that the presence of the drain, by promoting inflammatory reaction and tissue solution, contributed to opening of the cystic duct. It seems much more likely that it was pressure in the biliary passages which produced seepage from an insecurely closed stump.

CASE 5 Operation November 12, 1932. The gall-bladder was only slightly thickened and electro-surgical cholecystectomy was not at first planned. The cystic duct and artery were dissected free, cut off and tied separately. Then it became necessary to terminate the operation speedily on account of difficulty with the anesthesia. The vesicle was too firmly attached to the liver and too vascular to allow stripping it away, so it was split, stones removed, the lower third cut away and the remainder hastily coagulated. Penrose drains were placed and the abdomen closed. The patient soon developed a postoperative pulmonary collapse, probably from a plug of mucus inhaled at the time of operation. There was also considerable wound infection. The sinus persisted, an injection of iodized oil six weeks afterwards disclosed a connection with a spherical cavity deep in the abdomen, probably a sac formed by regeneration of the gall bladder and its mucosa.

The second operation was performed December 28, 1932. Through a transverse incision below the sinus tract, the sac of regenerated gall-bladder tissue was located, split open, and coagulated thoroughly, drainage was instituted. The wound closed in due time, but the patient continued to have indigestion and a great deal of discomfort in the right upper quadrant of the abdomen.

The third operation was performed July 1, 1933. There were tremendous fibrous adhesions in the form of a cord as big as the thumb, attaching the duodenum to the site of removal of the sac of

regenerated gall bladder, which had to be cut away with sharp dissection. The common duct was not involved in adhesions, or dilated. Careful palpation revealed no thickening or stones. Drainage was instituted. The patient made an uneventful post-operative recovery. The pain, however, continued over the right upper quadrant of the abdomen and over the right lower chest in front. X-rays demonstrated that there was an adhesion producing partial obstruction of the jejunum. After consultation it was decided to operate for the obstructing adhesion and explore the common bile duct. This was done but no stones were found in the duct. Again the patient made an uneventful postoperative recovery.

The pain over the right front chest continued, more or less constant, of an aggravating nature, at times with sharp twinges. Finally in view of lack of other symptoms it was considered that this symptom was not referable to the biliary or alimentary systems. Careful study of the spinal canal indicated that there was some sort of block at the nerve roots supplying this area. Exploration revealed adhesions from an old arachnoiditis producing marked pressure on the nerve roots. This was relieved, and the patient made a perfect recovery.

Comment. Several lessons are to be learned from this case. (1) If the tissue of the gall-bladder is to be treated electro-surgically, it must be thoroughly destroyed. Any remaining mucosa may regenerate to form a miniature gall-bladder or permanent sinus tract. (2) Coagulation of any considerable mass of tissue in this region may result in pronounced fibrous tissue proliferation, with dense adhesions. This is one of the disadvantages which have to be accepted with this method, indicating that it is best adapted to those cases where there are already pronounced adhesions, or fibrosis of the gall-bladder. (3) This patient was addicted to alcohol and after so many operations had developed a morphine habit which masked symptoms. The exploration of the common bile duct at the last operation was not necessary, though the patient had such definite symptoms that several experts in this field deemed it advisable. After the greatest difficulty the correct diagnosis of arachnoiditis with nerve root pressure was made and relieved by operation. Certainly this is an unusual condition to be confused with symptoms of disease of the biliary system.

CASE 6 Operation June 14, 1933. This patient had persistent jaundice. A thickened and narrow fibrotic gall bladder with a little mucus in it was treated electro-surgically in the usual way. The common bile duct was opened and a single, non-faceted stone removed. A probe could not be inserted into the duodenum, but no stone could be palpated, and on account of the rather precarious condition of the patient it was decided not to open the duodenum to approach the ampulla of the common bile duct.

The patient made a good recovery but when the sinus tract closed she again became jaundiced, developed chills, hyperpyrexia, and died. Autopsy showed a stone firmly impacted in the ampulla of the common bile duct, with cholangitis and multiple abscess formation in the liver.

Comment There was no difficulty here with the application of electrosurgery, it was in over looking a stone in the common bile duct, or in considering further exploration inexpedient. In this work the high frequency current has not been used in incisions of the common bile duct on the theory of producing just as little tissue destruction here as possible. However where the duct is dilated and thickened, with considerable inflammation and a tendency to bleed, incision with the "cutting current" and heavy dehydration would be helpful in controlling hemorrhage which is sometimes very troublesome after incisions of the duct.

CASE 7 This patient was operated upon three years before at another hospital a cholecystectomy and appendectomy being performed. The sinna had persisted in discharging mucopurulent matter at intervals. An attempt at sterilization of the tract was made by injection of antiseptics for several days before the second operation October 3 1933 (Massachusetts Memorial Hospitals). From an elliptical incision dense adhesions about the entire tract were dissected with sharp instruments. Hemorrhage from the liver was controlled by deep electrocoagulation. The thickened thumb-sized gall bladder was deep in the abdomen. Upon splitting longitudinally it was found to contain mucopurulent material and several mulberry gallstones about a centimeter in diameter. The cystic duct had apparently been closed by fibrosis. Some of the gall bladder tissue was cut away with the cutting current and that left attached to the liver was scooped away with the loop electrode. The gall bladder fossa was treated by electrocoagulation and fulguration. Penrose drains were inserted to the gall bladder fossa.

There was a slight discharge of bile for a few days followed by more or less serous oozing which was still present in small amounts at time of discharge twenty five days after the operation. Three months later the wound was solidly healed though there was considerable bulging of the upper abdomen from absence of the right rectus muscle.

Comment The most important lesson to be learned from this case is that a patient who is in good enough condition to have an incidental appendectomy performed should have a cholecystectomy instead of a cholecystostomy. Furthermore, from the character of the stones it is likely that they were produced in a straw berry gall bladder long previous to the first operation three years ago. They must have been overlooked in the gall bladder itself at the time of the cholecystostomy. The factor causing the persistent discharging sinus may have been the postoperative closure of the cystic duct by fibrosis.

CASE 8 Operation February 24 1934 The gall bladder was chronically inflamed 6 to 7 millimeters in thickness. It contained a muddy brownish-green material and stones no mucosa being present. No outlet to the cystic duct could be seen. The redundant portions were trimmed away as usual and the remaining parts thoroughly coagulated by inserting the needle at intervals over the surface to destroy the large amount of excess fibrous tissue

of the gall bladder. Two Penrose drains were inserted.

There was a moderate serous discharge for a few days the patient making a good recovery and leaving the hospital twenty three days after the operation.

Comment Here is one case in which, as it worked out, drainage was not essential. However, it did not appear to have delayed her recovery, and there was no way of knowing at the operation that the cystic duct (although its opening could not be found) would not open up afterwards, discharging bile into the peritoneal cavity.

CASE 9 Operation March 12 1934 The gall bladder was chronically inflamed twice normal thickness. It was treated in the manner previously described except that the gall bladder fossa was closed by a continuous stitch. The cystic duct in this case was dissected free and tied. Penrose drains were inserted.

There was no drainage of bile. She was discharged the eighteenth day after the operation the wound dry and in good general condition.

Comment Since the cystic duct was carefully tied in this case, and the fossa closed with a stitch, with no apparent hemorrhage, probably it would have been safe to omit drainage. However, recovery was not apparently delayed by it.

CASE 10 (Wyman House Cambridge Hospital) Operation June 4 1934 The gall bladder was thickened and contained stones. It was removed in the usual manner a soft tube was attached to the stump of the cystic duct.

The patient had some pulmonary congestion and made a rather slow postoperative recovery. The wound healed after about two months.

Comment This patient was old and had been refused operation by competent advisers on account of being a poor surgical risk. It is almost certain that electrosurgical cholecystectomy allowed removal of the gall bladder with greater safety, and that drainage with the tube was a wise procedure. At least here is a patient, who was a poor risk, in whom both these devices were used with success.

CASE 11 A man over sixty had had a total thyroidectomy for angina pectoris. Study showed the presence of gallstones and the patient was having such severe attacks of what was almost entirely biliary colic that in face of the danger he decided to have surgery attempted for relief. Operation July 10 1934 The gall bladder was only slightly thickened not adherent, but contained stones. An effort was made to remove it under local anesthesia but either had to be given. Although cholecystectomy only with removal of stones was planned at first, the gall bladder was so easily delivered that electrosurgical cholecystectomy was decided upon. It was done in the usual manner.

The patient died the afternoon of the day following the operation having been in apparently good condition until just before death. Necropsy demonstrated an infarct of the heart which had been

present before operation The coagulated tissue of the gall bladder had remained attached to the liver but there was no damage to the liver itself or to adjacent structures

CASE 12 Operation July 16, 1934 The gall-bladder was twice normal thickness, not adherent. Removed by the usual electrosurgical method, drained

Uneventful postoperative recovery and, although an arthritic cripple, the patient was discharged from the hospital twenty days after the operation, wound solidly healed

Comment Drainage in this case, although probably not necessary, did not apparently delay his recovery

CASE 13 Operation July 27, 1934 Gall bladder was only slightly thickened, nonadherent, contained stones The usual electrosurgical operation was performed and drainage employed

Although the patient made a good recovery, drainage of mucopurulent material continued for about a week Discharged the thirteenth day

Comment It is to be noted that in this patient the gall-bladder was neither sclerotic nor acutely inflamed Probably the drainage of mucopurulent material could have been avoided if the regular sharp dissection operation had been performed Apparently then in thin-walled gall-bladders electrosurgical cholecystectomy is not advantageous

CASE 14 Operation October 19, 1934 The gall-bladder was thin walled, non adherent and contained stones The usual electrosurgical procedure was carried out, with drainage

The patient made a good immediate recovery Drainage of seropurulent material continued for about a week The sinus closed after about two weeks but at the end of a month there was swelling in the wound and about four ounces of pus were evacuated After this, rapid recovery ensued

Comment In most of the cases observed where electrosurgery has been employed with drainage, there has been a discharge of considerable muco- or seropurulent material for one to two weeks With ordinary gall-bladder cases, where clean dissection has been made, there has not been a similar discharge This indicates the necessity for drainage after electrosurgical cholecystectomy, and again that with a thin-walled gall-bladder which can be removed cleanly by sharp dissection electrosurgery is more of a disadvantage than otherwise

CASE 15 Operation October 20, 1934 Gall bladder thin walled, not adherent Removed by the usual electrosurgical method It was accidentally torn away from the liver slightly on one side Hemorrhage, there, was controlled by coagulation and fulguration of the liver tissue The cystic duct was tied and drainage instituted Since the patient had had symptoms pointing to the appendix, this was removed through a separate incision

This patient had an immediate hyperpyrexia and died three days after the operation There were no signs of intra abdominal disturbance There had been severe reactions to intravenous administration

of glucose Necropsy showed nothing significant in the abdomen The operative site was surgically clean with a small coagulum of gall bladder tissue remaining attached to the liver without apparent damage to that viscus or to any other surrounding structures The patient had a severe acute and chronic gastritis, and it is believed that she was alcoholic, which may have had something to do with her death

Comment It is almost certain that the high-frequency current did not produce damage of the liver or other tissues which led to the death of this patient In none of my experimental animals or other patients have such results been observed

CASE 16 Operation December 5, 1934 Pronounced adhesions of the omentum and other viscera to the gall bladder and liver The gall bladder was shrunken to the size of a thumb and markedly sclerotic It was opened with the "cutting current" and contained only mucopurulent material The cystic duct had apparently been closed by fibrosis A little of the gall bladder was trimmed away with the "cutting current," practically no bleeding being encountered, the rest of it was coagulated and fulgurated The common duct in this case had been pulled up and markedly angulated by the shrunken gall bladder, a stone about a centimeter in diameter was removed from the duct Its outlet was dilated to about a centimeter with graduated probes A T-tube was placed in the common duct This patient was moderately jaundiced at the time of operation Although she did not bleed excessively, care was taken to stop all bleeding points

A few days after the operation, material resembling old blood began to be discharged in considerable quantities from the drainage tract around the T-tube, coincidental with lowering of the red blood count and the appearance of a sizable tumor in the right side of the abdomen Blood transfusion was given and the bleeding stopped After a few days a colon-bacillus pus began to be discharged, the whole mass, probably a hematoma, was reduced considerably in size but pressure on it below would cause the welling out of pus, the quantity gradually lessened and the patient recovered

Comment It is possible that the hemorrhage, resulting in the abdominal hematoma, arose from the coagulated gall-bladder tissue remaining attached to the liver, but this is doubtful because the amount of tissue was very small and no definite bleeders were encountered in it It is possible that the hemorrhage came from some adhesion which had been cut, or from the incision into the common bile duct, or from damaged vessels of the abdominal wall Since this is the only patient of the group who had postoperative hemorrhage it would seem that other circumstances than the use of electrosurgery account for it

Three of the sixteen patients died after electrosurgical cholecystectomy by the modified Pribram method The cause of death in the first was a blockage of the common bile duct by stone, overlooked at the operation, which led to recurrence of jaundice, cholangitis, and multiple liver abscesses The second death came in a patient who was known to be an extremely

poor risk, having had a thyroidectomy for an *gyna pectoris*. Biliary colic, however, rendered life intolerable. Postmortem examination revealed that a cardiac infarct had been present at the time the operation was performed. Yet, in neither of these cases would the method of operation seem to have had anything to do with the unfortunate result. The third patient was supposed to be a good operative risk. The gall bladder itself was not severely diseased and could have been removed readily by the usual dissection method. The patient developed immediately following intravenous glucose injection, a hyperpyrexia and died the third day, having been in coma most of the time. There had been no unusual abdominal signs. Necropsy showed that the operative site was clean, with no damage to the liver or other viscera. The gall bladder fossa contained the coagulated tissue that remained of the gall bladder. All ducts were normal. There were no signs of peritonitis or hemorrhage. There was a severe acute and chronic gastritis probably from alcoholism. In this case there was no obvious relation that could be made out between electrosurgery and death of the patient. Thus none of the three deaths in the sixteen cases of electrosurgical cholecystectomy could be attributed to the use of the electrosurgery itself. The only poor result was in the patient with whom on account of emergency at the operation there was insufficient time for thorough electrosurgical treatment of the gall bladder, resulting in partial regeneration which necessitated a second operation.

The best results experimentally⁴ as well as clinically were obtained with the markedly inflamed or sclerotic gall bladders. There would seem to be little advantage in using electrosurgery by this method at least, in the thin walled gall-bladder which can be readily dissected by the usual method.

DISCUSSION OF THE THOREK METHOD OF ELECTROSURGICAL OBLITERATION OF THE GALL-BLADDER

In November 1933³, and in July 1934⁴, Thorek published a criticism of the Prihram method⁶ of treating the gall bladder and presented important developments of his own. Briefly, the Thorek method is as follows. The field is isolated with moist laparotomy sponges. The gall bladder is aspirated. The cystic duct is ligated and divided. The gall bladder is incised from above downward with special diathermy scissors or knife. Stones are removed. The bile ducts are carefully explored. Redundant portions of the gall bladder are removed by diathermy, and the section remaining attached to the liver is thoroughly coagulated by contact with a flat electrode. Charring by fulguration is carefully avoided. The gall bladder tissue is coagulated to a sufficient depth to destroy the whole of it. The peritoneal edges are carefully approximated over the coagulated area with a running stitch. Then a graft of falciform ligament, either by

pedicle flap or free transplant, is stitched over the gall bladder fossa. The stump of the cystic duct is "peritonized", either by stitching the peritoneal edges over it or by attaching a free graft. The abdominal wound is tightly closed without drainage.

The method was employed in unselected cases of acute and chronic cholecystitis, cholelithiasis, gangrene of the gall bladder, early perforation with escape of bile, suppurative. Thorek's first article gives the impression that, given a patent common duct, drainage should never be employed if this method is used. In the body of the second paper, he admits the necessity of drainage in the case of inability to "peritonize" the cystic duct and gall bladder bed, but the summary says that in cases where the part of the gall bladder left attached to the liver is thoroughly coagulated and the falciform ligament superimposed, the cystic duct being "peritonized", drainage is entirely omitted, even in unselected cases, in which the method was used seventy five consecutive times without a fatality.

Results are important but no matter how apparently favorable they may be, other considerations, such as mechanical factors in surgical technique, physiological and pathological conditions, have to be taken into account.

A discussion of drainage follows. Thorek attributes almost every complication in biliary surgery to seepage of bile. In one hundred recent cases of cholecystectomy I have seen only one where a complication could be attributed to seepage, and it seems that this is not often serious provided the bile can find its way out readily through a drainage tract. The one case mentioned had pronounced seepage, probably from a needle hole in the common bile duct placed with the intention of exploration, but which was not carried out on account of poor condition of the patient. She had a profuse flow of bile through the drainage tract and died of subhepatic abscess.

Seepage of bile after cholecystectomy by the usual dissection method depends more upon the way the dissection is done than on any other factor. If the gall bladder is removed from below upward, the cystic duct and cystic artery tied, and then the gall bladder stripped off the liver with the fingers, a raw oozing surface will be left on the liver which will drain bile in considerable amounts whether or not there were aberrant cystic ducts running from liver to gall bladder. It is probable that the number of these ducts is overestimated, and that in the great majority of cases the reason why there is seepage after cholecystectomy is that an impatient surgeon snatches the gall bladder roughly off the liver. Explanation of bile seepage by the "blowing off" of the ligature from the cystic duct is overemphasized. There is no high explosive present to increase pressure in the biliary system. In the absence of mechanical blockage the common-duct sphincter can hardly

support more than three or four hundred millimeters of water. To be sure the ligature on the cystic duct probably does come off at times, but this is because the duct is friable or too much other tissue, including perhaps the cystic artery and considerable fat, is included in the ligature. This tissue rapidly liquefies and the ligature loosens. If the cystic duct is dissected cleanly, and tied not too tightly, with an adequate stump, there will almost never be leakage of bile from the stump. This has been demonstrated in our laboratory many times on dogs.

If the gall-bladder is removed from above downward, dissecting carefully, tying off all large strands of tissue which carry blood vessels (and possibly aberrant bile ducts), taking care to keep close to the gall-bladder and to leave a normal layer of areolar tissue over the liver, and then if the cystic duct is carefully dissected and tied according to the above method, there will almost never be seepage, whether or not the gall-bladder fossa and cystic duct stump are "peritonized." These cases when drained with soft Penrose drains, no gauze exposed, will discharge a little sero-sanguineous material for a day or two, and then heal quickly with extremely little discomfort to the patient.

With regard to electrosurgical cholecystectomy Thorek emphasizes the importance of covering the fossa of the gall-bladder with peritoneum, preferably after stitching it up, from a graft of the falciform ligament, either with a pedicle or free. He also emphasizes the importance of a peritoneal covering over the stump of the cystic duct. It would seem very difficult to make such a graft waterproof with a few stitches, and it is my opinion that if bile seeps from the liver bed, or the coagulum liquefies, or the ligature on the cystic duct loosens, the peritoneal graft will not be effective in preventing leakage, because there is almost always some tissue liquefaction and loosening of a catgut suture in a day or two after it is placed in the tissues. In ordinary cholecystectomy the important thing in preventing leakage is that the liver and the bile ducts must not be wounded, and the cystic duct must be dissected free and securely tied. Even though there is some liquefaction about the tie on the duct, the swelling from the inflammatory reaction in this firm tissue will maintain closure of the lumen. Such is not the case with a line of sutures.

Thorek speaks of "a sequestered coagulated mass" after electrosurgical cholecystectomy. In two dogs I removed sections of liver and stopped the hemorrhage by deep coagulation of the tissue by inserting the needle at intervals (circumvallation). One was sacrificed after two days and one after two years. In the former the coagulum was encapsulated by omental adhesions, in the other it had been absorbed. How-

ever, one dog in which electrosurgical coagulation of the gall-bladder was done according to Thorek's method was discovered one month later to have a large, cold, subhepatic abscess. In most of the patients upon whom electrosurgical cholecystectomy was performed, even by the coagulation method of Thorek, drainage of mucopurulent material persisted for a week or more. It seems preferable that this matter should come out of a drainage tract rather than be absorbed in the peritoneal cavity, or result in a collection of fluid.

Thorek, in his condemnation of drainage in surgery of the biliary system, makes no distinction as to type of drain. Drains in which gauze comes in contact with the tissues may produce all the dire results outlined by him, including erosion of vessels, predisposition to infection, etc. There is only one excuse for a gauze drain or gauze packing after cholecystectomy and that is a case of hemorrhage uncontrollable by another method. Even so, we recognize it as an evil. On the other hand, soft drains of gauze covered by rubber dam are not so easily accused of these sins. Of course there is a certain amount of fibrinous deposit and inflammatory reaction, with resulting slight increase of adhesions and the accompanying discomfort to the patient, but these are to be preferred to the danger of a collection of blood, bile, or infective material in the peritoneal cavity. The soft rubber tube-drain is for drainage of a tube, either the common bile duct or the stump of the cystic duct. Where the cystic duct cannot be adequately closed, the attachment of a rubber tube at or near its stump will give more effective drainage than the flaccid rubber drain, and the extra irritation of the firmer tube is preferable to the increased soiling from less effective direction of the outflow around soft rubber. I have, however, used rubber dam (Penrose) drains placed near an open cystic duct with excellent results. Thorek says "many patients succumb because of drainage." On the other hand, since drainage is still employed by the majority of surgeons, we might say that probably many more would have succumbed if drainage had not been done. If the gall-bladder can be dissected cleanly without wounding the liver, and a normal cystic duct freed and securely tied, or if by the electrosurgical method, the fossa of the gall-bladder is well coagulated, and the duct also securely tied, drainage is probably not essential. But if there is any expectation of oozing of bile from the liver, or leakage from the cystic duct, or bleeding anywhere, drainage should be employed. Drainage should always be employed in cases of markedly acute or gangrenous cholecystitis or empyema, no matter what surgical method of handling the condition is used.

In electrosurgical obliteration of the gall-

bladder, Thorek depends upon the collapse and coagulation of the vessel walls to prevent post-operative hemorrhage. It is doubtful that with the cystic artery and its larger branches this would always be sufficient. I prefer to clamp the larger vessels as they are out across when the redundant portions of the gall bladder are removed with the electric knife, and then tie them off with catgut. In the subsequent coagulation of the attached portion of the gall bladder these tied vessels are avoided. In other words more dependence is placed upon the tie than upon coagulation of the vessel walls.

The coagulum is likely to loosen sooner than the tie.

Thorek implies that shock is reduced by cutting and coagulating the tissue, thus not leaving exposed nerve ends as would be done by ordinary dissection. However, in operations upon the biliary system shock is also produced by other means such as prolonged or rough handling of peritoneum and viscera, exposure and chilling or by hemorrhage. When the gall bladder is cleanly dissected through a small incision care being taken to pack away viscera and stop all hemorrhage, the patients suffer extremely little shock, and make surprisingly easy and rapid recoveries.

SUMMARY

The clinical results on sixteen cases of electrosurgical cholecystectomy by a special method previously worked out on animals are presented. Essentially the method is as follows. The gall bladder is split to the cystic duct which is tied, the redundant portions of the gall bladder are removed by the electrosurgical "cutting current", the part of the gall bladder remaining attached to the liver is thoroughly coagulated.

The gall bladder best adapted to this method is one markedly inflamed or sclerotic. The method is not so safe or so effective in the non thick-

ened gall bladder, and the patients should be carefully selected with this point in mind.

The preferable current is the bi-terminal coagulating, contact should be made by the active electrode and the tissue treated to considerable depth. The tissue dissolving or "cutting current", and the uniterminal or "desiccating current" are not recommended for the treatment of the section of gall bladder left attached to the liver.

There were three deaths in the sixteen cases, none of them could be definitely related to the use of electrosurgery. The other patients made uneventful recoveries, for the most part with few complications, and the final results in all have been satisfactory, some of them having been followed for two and three years.

The question of drainage is discussed in the body of the paper. Where there has been considerable coagulated tissue left in place, where there has been pronounced inflammatory reaction, and where it has not been possible to tie the cystic duct securely, it has seemed advisable to drain. The type of drain has been the soft rubber tube inserted or attached to the stump of the cystic duct, or the rubber-dam cigarette drain (Penrose) with no exposure of gauze.

When the above principles are adhered to in carefully selected cases, those with markedly inflamed or sclerotic gall bladders, the method is recommended.

IRONIZED YEAST—KRUSCHEN SALTS—RADOX BATH SALTS

Among representations prohibited by the Federal Trade Commissioner's recent order to cease and desist were Ironized Yeast, Kruschen Salts and Radox Bath Salts. It has been alleged that Ironized Yeast will cure or relieve indigestion, constipation, nervousness, or skin eruptions except when such conditions result from a deficiency of vitamin B or iron or both, and that it will free users thereof of such diseases overnight. Other assertions banned were that Ironized Yeast is more effective than yeast and iron used separately and that persons deficient in shape or form will be transformed into well developed persons by its use, unless such representations are limited to improvement in health resulting from increased appetite and gain in weight where such persons have been deficient in vitamin B or iron or both.

WILL NOT REDUCE FAT

The "Kruschen Salts" case was decided by the

court, New York City. It arose on petition for review filed by F. Griffiths Hughes Inc. of Rochester, N. Y. The court affirmed the Commission's cease and desist order against Hughes Inc., and in its opinion discussed the findings and evidence at length, reaching the conclusion that the findings were supported by the evidence.

The order to cease and desist prohibited representations that "Kruschen Salts" constitutes a cure or remedy of obesity or that it will of itself reduce excess fat. Representations were also prohibited to the effect that "Radox Bath Salts" has therapeutic value when used in the bath, that it releases great quantities of oxygen when so used that its use at home combines the properties of world famous spas or produces the effects of treatment at such places that it stimulates or energizes the body or that it is imported from England.

Several reports on Kruschen Salts were issued by the Boston Bureau to local radio stations and newspapers as far back as 1930—*The Boston Better*

CASE 21401

PRESENTATION OF CASE

A sixty-three year old American housewife entered complaining of abdominal pain and constipation

For the past thirty-five years the patient complained of frequent severe aching pain in the pit of the stomach coming on regularly about 5 a.m. and relieved by lying on the left side. It never occurred at any other time and she had never tried soda or food for relief. Seven years before admission, after a fall in which she struck her back, she began to notice a dull aching pain in the left side of the back at the level of the waist which was brought on and made worse by long-continued standing and was relieved by sitting down. During the past four months it had been more severe even while lying down. It was more or less completely relieved by aspirin. Four months before admission she gradually became constipated, a condition which she had never had previously. This became more severe during the past month and on one occasion she went without a bowel movement for four days. There were no bloody, tarry or clay-colored stools. Five weeks before admission she began to complain of soreness over her entire abdomen around the right costal margin. At about the same time her appetite began to fail rapidly and since then she had nausea two or three times a day but no vomiting. She remained in bed almost constantly during the past month, during which time she lost ten pounds in weight. She had lost twenty-two pounds during the past seven months.

Her family and marital histories are non-contributory. There was no history of carcinoma or tuberculosis.

She had an attack of acute tonsillitis and grippe five years before admission and pneumonia one year before admission. At that time she was hospitalized for three weeks.

Physical examination showed a groaning woman constantly moving her lips and swallowing frequently. Her upper teeth were false. The tonsils were large and cryptic. The chest was slightly barrel shaped and showed bronchovesicular breathing. The heart was not remarkable. Abdominal examination showed an

enlarged, slightly tender liver and marked tenderness around the umbilicus. Upon pelvic examination three nodules, each about 1.5 centimeters in diameter, could be felt high up in the vaults.

The temperature was 98°, the pulse 80. The respirations were 20.

Examination of the urine was negative except for an occasional epithelial and white blood cell. The blood showed a red cell count of 4,180,000, with a hemoglobin of 60 per cent. The white cell count was 14,000, 71 per cent polymorphonuclears. The stools were hard and showed negative guaiac tests. A Hinton test was negative. A liver function test showed 0 to 5 per cent retention. The icteric index was 7, the nonprotein nitrogen of the blood 29 milligrams. A gastric analysis showed free hydrochloric acid. A guaiac test was negative.

X-rays of the chest were negative. A barium enema passed through the ileocecal valve. There was a considerable amount of air and fluid present. Several redundancies in the region of the sigmoid were noted. There was a questionable defect present in the region of the sigmoid. The cecum was never well outlined. No conclusions could be drawn because of the large amount of air present. A reexamination three days later showed that the entire large bowel as far as the rectum was still full of barium which had been introduced three days before. Another examination two days later showed that some of the barium introduced five days before was still present in the colon. No obstruction could be shown.

Operation was considered inadvisable and she was discharged nine days after admission. She did poorly while at home, gradually went downhill and died twelve days after discharge, approximately eight months after the onset of her illness.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM B BREED. This is a very unusual story and one gets the impression of some mechanical element here. She may have a diaphragmatic hernia. That is the first thing that comes to mind because of the nature of the pain, occurring as it does only at five o'clock in the morning and relieved by change in position, also because of the duration of thirty-five years. The backache of seven years' duration can best be explained on the basis of hypertrophic changes in the spine following a blow.

It seems to me that there are three other distinct phases to the present illness: (1) the mechanical story of upper abdominal pain occurring at five o'clock in the morning, and relieved by change in position, (2) the blow on the left side of her back which seems to be unrelated to the first symptom, and (3) the abdominal pain associated with constipation. Of

course, there is no reason why a person with diaphragmatic hernia should not develop cancer of the intestine

Except for the abdomen the physical examination does not contribute anything. The tonsils are large and cryptic. She might normally have an emphysematous chest at sixty. The heart was not remarkable. There is no question of a mass in the abdomen other than the liver. She is not vomiting so she presumably does not have upper intestinal obstruction. She has no fever, the pulse is good and the respiration is good. The physical examination does not help me very much.

She apparently was not given barium by mouth because of the question of obstruction, and so we cannot go farther into the question of diaphragmatic hernia which should interest us a good deal. It comes down really to the question of what this later process is. Presumably she has some low colonic obstruction somewhere in the region of the sigmoid although they say definitely no obstruction could be made out. There is a partial obstruction because of retention of barium and because at one examination they found some defect. She may have an annular carcinoma of the sigmoid, a scirrhous process which may not produce fecal blood but which gradually has been constricting the large intestine. They did not think they had to operate on her. The prognosis was evidently considered hopeless, so they sent her home. Apparently someone attended her while she was at home and succeeded in getting a post mortem examination.

We have to make a diagnosis on this case purely on the history. I am willing to say she had diaphragmatic hernia as a chance. I think the blow that she had was just incidental and that the pain was explainable on the basis of hypertrophic changes in her spine. Then, what caused her death? Presumably a new growth in the lower colon with metastases to the liver. I do not know what she had in the chest. She may have had fluid. Three masses were felt in the vaults. They may be metastatic nodules in the pelvic peritoneum or the broad ligaments.

Perhaps the tumor may have been primary in the ovary with metastases to the colon and to the liver.

DR. BENJAMIN CASTLEMAN. Ordinarily, Dr. Breed, if a tumor is primary in the ovary you should be able to feel an abdominal mass.

DR. BREED. Yes, that is true at this stage. Of course, there is tenderness around the umbilicus. That does not mean anything to me at all. Does it mean anything to anyone?

A PHYSICIAN. Could it mean pancreatic involvement?

DR. BREED. Yes it could. I think that she has malignant disease in the lower abdomen, but where it is primary I believe would be somewhat of a guess. We have

nothing that will locate it either in the pelvic organs or in the sigmoid.

A PHYSICIAN. Do you think she has metastatic involvement in the liver?

DR. BREED. Yes.

A PHYSICIAN. Could that fall have precipitated a metastatic process in the spine?

DR. BREED. If you have so much metastases to the spine that a fall would cause symptoms I should think she would have had pain before, because you often get pain in metastatic carcinoma of the spine before you find anything by x-ray at all. Aspirin does relieve pain from malignancy surprisingly well. In this case, however, it was used over a period of seven months and that would make it seem benign.

A PHYSICIAN. Do you think that malignancy around the duodenum or pancreas would cause that pain in the back?

DR. BREED. Yes, but we have the story that it followed a blow. A person of sixty-five who has a sharp blow in the back may very often have continued pain because of hypertrophic changes. I would rather take that than go afield, that is what I think is afield, and try to explain it by metastatic disease.

A PHYSICIAN. Do you think that the nodules point in any way to abdominal Hodgkin's disease?

DR. BREED. I should not think so since they were felt on pelvic examination in the vaults and broad ligaments and there were no masses anywhere else.

CLINICAL DIAGNOSIS

Carcinoma of the colon with generalized metastases.

DR. WILLIAM B. BREED'S DIAGNOSES

Carcinoma of the sigmoid with metastases to the liver and pelvis.
Diaphragmatic hernia?

ANATOMICAL DIAGNOSES

Adenocarcinoma of the tail of the pancreas with metastases to the peritoneum, pelvis, uterus, liver, diaphragm, mesenteric and retroperitoneal glands, lungs and pleura.
Endocarditis, acute bacterial, mitral and aortic.

Endocarditis, chronic rheumatic, aortic and mitral.

Thrombophlebitis of the left common iliac vein.

Pulmonary thrombosis.

Pulmonary infarction.

Pulmonary atelectasis.

Arteriosclerosis. Marked aortic and coronary, slight renal.

PATHOLOGIC DISCUSSION

DR. CASTLEMAN. We found the abdominal cavity completely filled with tumor. All the

glands along the aorta, mesentery and omentum were replaced with tumor. This was especially marked around the sigmoid and rectum, a fact that may explain her recent constipation. The pelvis was completely filled with tumor but we found no evidence of any intrinsic disease of the colon or pelvic organs. The site of the primary tumor was the tail of the pancreas, which apparently accounts for her left back pain. The tumor measured about five centimeters in diameter and was hard and fibrous. The medial margin of the tumor was poorly defined as it merged with the body of the pancreas. Histologic examination showed a well-differentiated scirrhous adenocarcinoma. The liver was filled with metastases and weighed 2,000 grams. There were also metastases to the lungs and gall bladder, the latter possibly responsible for her right upper quadrant pain. The lungs showed pulmonary thromboses with infarction which probably were embolic from a well-marked thrombophlebitis of the left common iliac vein. In one of the infarcts there was a small focus of metastatic carcinoma. She had a terminal acute bacterial endocarditis in addition to an old chronic rheumatic endocarditis without stenosis of the mitral and aortic valves. The heart itself was not enlarged.

DR BREED Was there any diaphragmatic hernia?

DR CASTLEMAN None were noted but one may have been present and, if so, it was probably a small one. There was no evidence of peptic ulcer.

DR BREED I do not see how you can explain her symptoms of thirty-five years' duration except on the basis of a small mechanical defect.

A PHYSICIAN Would gall stones ever produce anything like that?

DR BREED I do not think so. It is a mechanical story.

A PHYSICIAN How often do you see carcinoma originate in the tail of the pancreas?

DR CASTLEMAN It is very rare. We recently had a patient with a similar story in which a clinical diagnosis of carcinoma of the colon with liver metastases was also made. In this case the tumor was in the body of the pancreas. Tumors of the body as well as the tail of the pancreas almost always have left upper back pain.

DR BREED Yes, the pain in the left back here turns out to be a very important symptom.

A PHYSICIAN How much involvement of the pancreas do you have to have before you get sugar in the urine?

DR BREED Considerable.

A PHYSICIAN Apparently the pain about the umbilicus indicated pancreatic involvement?

DR BREED Either that or liver.

A PHYSICIAN She probably did have arthritis of the spine.

DR CASTLEMAN Although an x-ray film of the spine was not taken, one of the knees showed hypertrophic changes.

CASE 21402

PRESENTATION OF CASE

A seventy-seven year old unemployed American entered complaining of vomiting.

Twelve years before entry the patient began having attacks of abdominal cramps with indigestion, flatulence and occasional vomiting. Four years before entry he vomited after meals about twice a week. He also had slight epigastric pain after meals relieved by soda. The pain occasionally came on at night and was severe enough to wake him. The vomitus was sometimes blood streaked. He also had cough with the production of a cupful of yellowish sputum a day, often streaked with blood. The cough and vomiting continued. One year before entry he began having occasional attacks of diarrhea characterized by five or six movements a day. These attacks occurred about once a month and lasted about two days. No blood, pus or mucus had been noticed in his stools. Three months before entry he began having dizzy spells in the morning and also some difficulty in swallowing. The epigastric pain had become worse and he frequently vomited small amounts about ten minutes after each meal. Two weeks before admission the vomiting became more frequent and for the past two days he had almost continuous vomiting. Questionable tarry stools had been noticed during the past few weeks.

His family and marital histories are non-contributory.

During the past two years he had had rather marked shortness of breath on exertion and some ankle edema. He had had nocturia two or three times for the past four years.

Physical examination showed an elderly, thin, cyanotic man in no acute distress. The skin was pale. The pupils were slightly irregular and fixed to light. His chest was pigeon-shaped in type, with an increased anterior posterior diameter. The spine was stiff. The right lung posteriorly was dull and showed numerous medium moist râles. The heart was not enlarged to percussion. There was a rough systolic murmur at the apex. The blood pressure was 140/90. The liver was felt two to three finger-breadths below the costal margin. The prostate was slightly enlarged and firm.

The temperature was 101.8°, the pulse 135. The respirations were 30.

Examination of the urine showed a slight trace of albumin and an occasional hyaline and granular cast. The blood showed a red cell count of 3,460,000, with a hemoglobin of 60 per

cent. The white cell count was 12 000, 86 per cent polymorphonuclears. The sputum was very tenacious and bloody and no tubercle bacilli could be found. The stools were negative. A Hinton test was negative. The non protein nitrogen of the blood was 56 milligrams. A phenolsulphonephthalein test gave 20 per cent excretion in one hour. A tuberculin test 1:1000 was negative.

X ray examination of the chest showed a soft, irregular mottled dullness extending from the right hilus region to involve the greater portion of the right lung field. The dullness was ill defined and hazy. The diaphragm on that side was flat and irregular in outline. The costophrenic angles were obliterated by a band of dullness which rose along the axillary line. The entire left lung field was clear. The heart was not remarkable. A gastrointestinal series showed slight irregularity on the lesser curvature, one inch in length just below the esophagus, and also an irregularity in the last inch of the stomach. This incomplete examination showed 100 per cent residue in the stomach.

The temperature remained around 101°. On the fourth day digitalis was begun. His condition remained about the same except for a chill on the fifth day. During the third week, however, he developed attacks of severe cyanosis associated with dyspnea and a weak rapid pulse. Several times he appeared dead but was revived with caffeine. He died approximately three weeks after admission.

DIFFERENTIAL DIAGNOSIS

DR. OLIVER COPE. In order to arrive at a diagnosis in this case it is necessary to limit colonic symptoms, demonstrable gastric disease, and unusual extensive unilateral disease in the chest. It would definitely be easier to make two diagnoses but I shall try to account for them all in one.

The history suggests a long standing gastric lesion. The duration of twelve years suggests an ulcer as a background although syphilis must be considered. It would be rare for a primary malignancy to have lasted so long. The episode of diarrhea one year before entry suggests to my mind a possible perforation into or involvement of the colon. The difficulty in swallowing might be due either to involvement in the cardia or compression of the esophagus by a mediastinal mass such as metastatic carcinomatous lymph nodes. The dizzy spells I think we can dismiss as part of the cachexia. The recent frequency of vomiting very shortly after the meal suggests again involvement of the esophagus or of the cardia. The tarry stools are of no help since malignancy, ulcer, syphilis or other infection can cause them. The shortness of breath and ankle edema are also explicable on the basis of the cachexia and the anemia. In the presence of an enlarged pros-

tate, nocturia is of no importance in the differential diagnosis.

On physical examination the cyanosis is the first thing of interest, since this points to the pulmonary complication. The irregular and fixed pupils must be taken seriously, even in the presence of the negative Hinton test, and lend definite weight to the diagnosis of syphilis of the atomacab. I shall refer to this later in relation to the chest findings. The record states that the liver was felt well below the costal margin but it does not say whether the liver was irregular or tender. The enlarged liver may therefore be either chronic passive congestion or possibly metastatic malignancy. Gumma of the liver is also possible.

The laboratory data are not helpful except for the negative Hinton and the absence of tubercle bacilli in the sputum. The sputum is stated to have been tenacious and bloody but it does not state whether other cells or spores were present. If actinomycosis were present in the lung the spores probably would have appeared in the sputum. The elevated nonprotein nitrogen could be accounted for by either the high intestinal obstruction, which was obviously present, or by diminished renal function from an enlarged prostate. It is of no significance in the diagnosis of the primary disease.

The x ray findings are of course most important. The physical examination has already told us of disease in the right lung. That the disease by x ray is limited entirely to the right side is of importance since, were the areas in the right lung due to blood borne metastatic malignant disease, they should also have appeared on the left side. This is not so true, however, of metastases from the abdomen to the chest by the lymph channels. The x ray is also of aid in that it shows no shift of the mediastinum. Had there been compression of a major bronchus by either a primary tumor or by a tumor metastatic to the glands in the mediastinum there should have been either complete bronchial occlusion with atelectasis or partial occlusion with probable abscess formation. The x ray suggests neither atelectasis nor an abscess localized to the area of any one bronchus. The findings in the lung are not consistent with the usual type of bronchopneumonia since again the left side is not affected. It is not a terminal lobar pneumonia. The diffuse areas of mottled dullness with a fixed low diaphragm suggest to me a chronic infection. It could also be produced by syphilis, actinomycosis, lymph borne malignancy or lymphoma. The gastrointestinal x rays bear out the probable diagnosis made from the history of involvement high in the stomach. Involvement of the stomach in two places and also possibly of the colon suggests lymphoma. From the history the most

probable diagnosis would be a gastric ulcer which later became malignant with mediastinal and pulmonary metastases. The x-ray findings make this less likely as there is too little in the stomach and disease on only one side in the chest. Lymphoma is a possible diagnosis but the chest plate suggests infection more than malignancy. The negative Hinton rules out one of the best diagnoses to explain both the gastric and pulmonary findings. In spite of the fixed pupils I am forced to abandon the diagnosis of syphilis. Tuberculosis could also account for the whole picture but the absence of bacilli in the sputum absolutely rules this out in view of the active disease in the chest. I am left with those infections which may present a picture similar to widespread tumor formation, the most likely of these is actinomycosis. It is possible but not probable that actinomycosis would have lasted as long as twelve years without a sinus in the chest.

CLINICAL DIAGNOSES

Carcinoma of the lung, probably metastatic
Arteriosclerosis
Arteriosclerotic heart disease

DR OLIVER COPE'S DIAGNOSES

In order of preference
Actinomycosis
Lymphoma.
Gastric malignancy with pulmonary metastases

ANATOMIC DIAGNOSES

Duodenal ulcer, obstructing
Arteriosclerosis marked coronary, aortic, renal and cerebral
Myocardial infarct, left ventricle
Pulmonary abscess, right
Thrombosis with occlusion of a branch of the pulmonary artery, right
Straddling non-occluding thrombus of the secondary bifurcation of the pulmonary artery, left.
Pulmonary infarct, right
Mural thrombi of the aorta.
Organized thrombus of the superior mesenteric artery
Small infarcts of basal ganglia
Focal necrosis of the adrenal
Hydrothorax, right
Peripheral edema
Pleuritis, chronic fibrous, bilateral
Diverticula of the large intestine
Perisplenitis, old

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY Dr Cope's effort to fit all the complicated sections of the puzzle together on the basis of a single diagnosis is

always the most interesting way to treat a differential diagnosis. In the majority of cases in which it can be done, moreover, it probably leads to success. This method, however, is apt to be more fruitful in the case of young or middle-aged people than in the case of men who have reached the senile period. In many of these individuals the various parts of the mechanism often seem to break down simultaneously, much like the famous one-horse shay. A single case often presents in itself a veritable museum of different pathologic conditions, each of which in itself might well have been adequate to cause death. The present patient was an example of such a situation and I believe a correct diagnosis of any large proportion of his various ailments was quite impossible.

The single most important lesion and the one which undoubtedly accounted for his gastric symptoms and vomiting was a deep penetrating ulcer on the posterior wall of the duodenum which had constricted the lumen to a diameter of barely a centimeter and deeply invaded the head of the pancreas. We were not able to find in the stomach itself any second lesion and the esophagus was likewise negative.

The second important finding for which almost no leads except edema and dyspnea were provided in the record was an extreme grade of coronary sclerosis with complete old calcified obliteration of the descending branch of the left coronary artery and a large area of infarction in the anterior wall of the left ventricle. This showed both old fibrous scarring and fresh necrosis of muscle fibers, indicating that the lesion had not been produced all at one time. A rather large, fairly adherent thrombus overlay the infarct on the ventricular surface. The lungs showed a rather complicated combination of infarction, abscess and pneumonic consolidation. One large abscess, 4 centimeters in diameter, was found near the hilum of the right lung. Several partially adherent pulmonary emboli were present in the arteries of both right and left lungs. The most probable explanation would seem to be multiple septic emboli with secondary abscess formation. A totally unexpected finding was another organized embolus partially occluding the mouth of the superior mesenteric artery. This may have had something to do with one of the episodes of diarrhea in the earlier part of the history. The liver, far from being large, was markedly atrophic and weighed only 850 grams. It was not cirrhotic, however, and the sizes of all the other organs confirmed the impression of senile atrophy. Other findings which probably have nothing to do with the symptomatology were severe atheroma of the aorta with multiple ulcers and adherent thrombi, scattered small areas of infarction of the basal ganglia, marked fibrous pleuritis, benign prostatic hypertrophy and multiple uninflamed diverticula of the large intestine.

"POLIO" VACCINES

With the wave of infantile paralysis that has come rolling up from the South, there is a new surge of alarm, and, as a consequence, a revival of fervent hope that some means may be found to shield our young against its afflictions. Parents do not have to be persuaded or urged to volunteer their children for the trial of new biologic agents—they demand them. It was this parents' plea that disrupted the carefully planned investigations on the value of convalescent serum. Means for a careful appraisal were easy to devise, impossible to carry out. Each in a individual lot of convalescent serum should have been tested for its potency, the serum should have been given only to alternate cases, and in large amounts. With these provisions the supply of serum would have sufficed for only a small proportion of the cases that eventually received it. Donors were all too few, the preliminary testing of the serum was expensive but the main difficulty encountered was the

inability of our special investigators to with hold this promising agent from any stricken child. The plea for serum was too impassioned to be resisted. Our sentiment overruled our reason. The Australians, especially Jean Mac namara, were more coldly scientific. They were more interested in ultimate rather than proximate results, and unless we are mistaken, they, with reason, still have faith in the specific inhibiting action of convalescent serum on the unknown virus of anterior poliomyelitis.

We grant that the final results of the American trials are unimpressive, but we still feel that they were not fair trials, and we hold that the true value of convalescent serum is yet unknown. We cannot detach our thoughts from the facts that this disease, by an attack, sets up in nearly all cases a lifelong immunity, and that the serum of those recently convalescing has strong protective power against the virus. This power may not be great enough to arrest the progress of the infection once it is established, but we feel that we should not say that it has not this power until all the resources of exact experimental measures have been exhausted.

From serum we have now turned to vaccines, and again the situation is repeated. Thousands of mothers beg for its trial and the supply of vaccine is limited. Before we again let our eagerness confuse our reason, it may be well to consider some of the facts of the matter.

The manner in which the vaccine is prepared may or may not be of importance—whether the living virus in the infected monkey's cord is rendered innocuous by formaldehyde or by a soap. Experience only can tell which method, or some other yet untried, is the most efficacious. But lest we decide too hastily from the results of a few treatments (and it takes many subjects to make the results significant), it may be well to recall some of the information regarding active immunization that has come from the Harvard Infantile Paralysis Commission. If we remember their laboratory experiences correctly, it would seem that the injection of subinfective amounts of living, virulent virus, repeated many times, failed to produce sufficient active immunity to protect a susceptible monkey against a subsequent inoculation with a fatal dose of virus. If the active, living virus thus administered, fails to establish immunity, it would seem reasonable to expect that a killed or greatly attenuated virus would be no more antigenic. There may, of course, be some biological law operating here of which we are ignorant, but we cannot heartily share the optimism that now prevails over the possibilities of vaccine treatment.

At the risk of being called even more pessimistic, we venture to call attention to a question of simple arithmetic. If we grant with Avecock and others that an appreciable proportion of

the population have at some time been infected with the virus of poliomyelitis and thereby have become immune, then any rational approach to the evaluation of a prophylactic agent would include a preliminary test for susceptibility. For each test one monkey would be required. Since, for the production of vaccine by present methods, one monkey furnishes at the most, sufficient vaccine for ten injections, then each single injection would require one-tenth monkey. If we are to determine if the vaccine treatment has established active immunity then another monkey is called for, and if we are to ascertain the period for which protection exists, then still more monkeys would be needed—one monkey for each individual test. Another factor in our equation is the number of Rhesus monkeys available. Disregarding the monkeys for all supplemental immunity tests, excepting the first one after the vaccine injections, we could express the problem, in its simplest terms, in an equation somewhat in this form

Let A equal the number of children born each year, and

A¹ the number found to be immune by the susceptibility test

Let M represent the number of monkeys required for test and vaccine production, and

M¹ the number of monkeys available each year, then with

R standing for the ratio of the monkey supply to the demand

$$\frac{AM + (A - A^1) \frac{M}{10} + (A - A^1) M}{M^1} = R$$

It is not necessary for statisticians to supply the exact figures for A, M and M¹, and it requires no profound knowledge of mathematics to arrive at R. Its value is significant.

However, such baffling problems have never discouraged the scientist, and we favor the trial of any agent or procedure that will spare us from the afflictions that anterior poliomyelitis imposes on us. But we hope that our eagerness will be tempered with reason and that any trial of any preventive or curative agent will be conducted with full and rigid controls, so that we may be spared the disappointment that has too often followed some of our earlier attempts.

CONSERVATION OF HEALTH

'CONSERVATION is the effort to insure to society the maximum present and future benefit from the use of natural resources.'

If man is regarded as a part of nature and the mind is at least natural in its origin, we may without violence, transfer to man the application of some ideas which have come into

prominence in dealing with extra-human factors in national life.

The physician is concerned with disease, its relief, its cure and often as an after-thought, its prevention. The negative view of health as being "not sick" has often received just criticism. The idea of health as something positive has been emphasized by persons interested in preventing disease and in public health.

But most persons though perhaps fearing disease are actually well most of the time, and the needed point of view is less the prevention of disease and more the conservation of the health we already possess. There is here a shade of difference in meaning and emphasis which colors the whole outlook. For those who are sick, health is something to be achieved. For the well, it is a conservation of what we have. We eat, we work, we play, we sleep, not to prevent disease but to conserve and preserve that which we already have, that is to say, our well.

We have no word which connotes nicely just what we have in mind when we refer to a person who conserves health. "Health conservationist" is barbaric. "Hygienist" we cannot rescue from its present plight. A "conservative" is popularly anathematized from the start.

Yet it is a very fine and at the same time a very robust idea that we should conserve the resources of mind and body which have been given us by nature, and that we should by art insure to ourselves and society the maximum present and future benefit which those resources make possible. It represents a point of view we should more often seek to occupy, until it dominates our instinctive and habitual reactions.

THE REAPPOINTMENT OF DR HENRY M POLLOCK

READERS of the *Journal* will be glad to know that Governor Curley has reappointed Dr Henry M Pollock, Superintendent of the Massachusetts Memorial Hospitals, as Associate Commissioner of the Massachusetts Department of Mental Diseases and that the appointment has been confirmed by the Executive Council. Dr Pollock who had had many years' experience as Superintendent of a State hospital before coming to Massachusetts, has served continuously, and with distinction, as Associate Commissioner of the Department of Mental Diseases since it was organized in 1916 and has given freely of his time and service without any compensation. The *Journal* and the medical profession it represents are appreciative of this recognition by His Excellency, Governor Curley, of efficient service in developing and maintaining the high standards of this important Department of the State.

POSTPARTUM HEMORRHAGE—ETIOLOGY
AND TREATMENT

Much bleeding is unusual between the birth of the baby and the expulsion of the placenta. Should it occur one must consider as possible causes, lacerations of the genital tract or cervix and partial separation of the placenta.

Hemorrhage occurring after the delivery of the placenta may be due (1) to a flabby, atonic, poorly contracted uterus, (2) retention of a portion of the placenta, or (3) laceration of the cervix.

The diagnosis is usually easily determined and must be made especially in all cases of severe hemorrhage so that prompt and appropriate treatment may be given to check it.

Bleeding from a lacerated vessel in the perineum or labia is easily discovered and stopped by ligation or suture.

Although it is always lacerated during labor the cervix is seldom the source of much bleeding or it does not cease spontaneously. If after the placenta has been delivered and the uterus is firmly contracted bleeding continues unaffected by contraction or relaxation of the uterus, cervical lacerations must be considered as the possible cause. This is especially probable in cases of difficult operative delivery undertaken when the cervix was not fully dilated and always when the presenting part has been pulled through the cervix. In such a situation the cervix must be carefully examined under direct vision and any extensive lacerations closed by sutures.

Partial separation of the placenta is a frequent cause of bleeding. So long as it remains attached over its entire area and the uterus is contracted hemorrhage does not occur. While partial detachment may occur spontaneously it is often the result of undue haste in attempting to express the placenta. Gentle kneading of the uterus will usually stimulate contractions and check the bleeding. Pituitrin given intramuscularly is a powerful oxytocic and in many hospitals it is given routinely immediately after the birth of the baby. Usually the technique of merely holding the uterus plus the effect of pituitrin, which may be repeated

A series of short selected articles by members of the Section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the Section.

Dr Thomas C Quirk of Watertown, Associate Medical Examiner of the Seventh Middlesex District.

These appointments were confirmed by the Council as were the nominations of Dr Brickley and Dr O'Leary previously referred to in this Journal

DR. SPECTOR BECOMES THE SECRETARY TREASURER OF THE BOSTON MEDICAL HISTORY CLUB

Dr Benjamin Spector, Professor of Anatomy, Tufts College Medical School, has been made Secretary-Treasurer of the Boston Medical History Club

RECENT DEATHS

MACDONALD—WILLIAM LEWIS MACDONALD, M.D. died in Malden, Massachusetts, September 24, 1935, at the home of his nephew, Dr W C MacDonald.

Dr Macdonald was born July 29, 1834, at Cambridge, New Brunswick, the son of Alexander Black Macdonald and Janet Hendry Macdonald. He came to Boston in 1859 and studied dentistry for a time, probably in connection with attendance at the Harvard Medical School, receiving his M.D. degree in 1865. He served as district physician on the staff of the Boston Dispensary but, preferring dentistry, followed that professional work until 1910.

He joined the Massachusetts Medical Society in 1865 and retired in 1903. He was also a member of the Massachusetts Dental Society, the Harvard Medical Alumni Association, and was a Mason.

Since 1900 he had lived with his stepdaughter, Miss Grace Wilbur Conant, 95 Mt Vernon Street, Boston.

He was taken ill while on a visit to New Brunswick a short time before his death and was taken to Malden in an ambulance. His wife died in 1900. Dr Macdonald is survived by his stepdaughter, a stepson, Walter A. Conant of Temple, New Hampshire, and several nephews and nieces.

PFEIFFER—ALBERT PFEIFFER, M.D., died in the Memorial Hospital at Albany, N.Y., September 24, 1935, as the result of an automobile accident August 27.

Dr Pfeiffer was a member of the Massachusetts Medical Society from 1919 to 1925.

He was born in Franklinville, New Jersey, in 1882. During his residence in Massachusetts, he was active in public health work, and for the past ten years had been director of the Division of Social Hygiene of the New York State Department of Health.

POSTPARTUM HEMORRHAGE—ETIOLOGY
AND TREATMENT

Much bleeding is unusual between the birth of the baby and the expulsion of the placenta. Should it occur one must consider as possible causes, lacerations of the genital tract or cervix and partial separation of the placenta.

Hemorrhage occurring after the delivery of the placenta may be due (1) to a flabby, atonic, poorly contracted uterus, (2) retention of a portion of the placenta or (3) laceration of the cervix.

The diagnosis is usually easily determined and must be made especially in all cases of severe hemorrhage so that prompt and appropriate treatment may be given to check it.

Bleeding from a lacerated vessel in the perineum or labia is easily discovered and stopped by ligation or suture.

Although it is always lacerated during labor the cervix is seldom the source of much bleeding or it does not cease spontaneously. If after the placenta has been delivered and the uterus is firmly contracted bleeding continues, unaffected by contraction or relaxation of the uterus, cervical lacerations must be considered as the possible cause. This is especially probable in cases of difficult operative delivery undertaken when the cervix was not fully dilated and always when the presenting part has been pulled through the cervix. In such a situation the cervix must be carefully examined under direct vision and any extensive lacerations closed by sutures.

Partial separation of the placenta is a frequent cause of bleeding. So long as it remains attached over its entire area and the uterus is contracted, hemorrhage does not occur. While partial detachment may occur spontaneously it is often the result of undue haste in attempting to express the placenta. Gentle kneading of the uterus will usually stimulate contractions and check the bleeding. Pituitrin given intramuscularly is a powerful oxytocic and in many hospitals it is given routinely immediately after the birth of the baby. Usually the technique of merely holding the uterus plus the effect of pituitrin, which may be repeated

A series of short selected articles by members of the Section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the Section.

if necessary, and waiting a reasonable period will be sufficient for the placenta to become separated and easily expressed. Rarely in the course of many deliveries the placenta does not entirely separate from the uterus and because of hemorrhage must be removed manually

Frequently after the placenta has been expressed considerable bleeding may occur because the uterus does not contract well. It is flabby and atonic. Such a condition often occurs after long-drawn-out labors or following difficult operative deliveries when the patient shows evidences of shock. Occasionally the situation may be alarming because of the amount of bleeding, the failure of the uterus to contract well and the fact that the patient is already in shock with low blood pressure and rapid thready pulse. The uterus should be held and kneaded to promote contractions. An ampule of ergot should be given intramuscularly and pituitrin repeated either intramuscularly or intravenously. Salt solution given by hypodermoclysis, hypertonic glucose intravenously, heaters and blankets and morphine or pantopon hypodermically should be used as supportive treatment for the relief of the surgical shock. If the condition of the uterus does not improve it should be packed to check the hemorrhage. Rarely a hysterectomy may be necessary because of uncontrollable bleeding. A transfusion, of course, should be done if the patient has bled enough to make it necessary.

Every placenta should be carefully examined to make certain that it is intact and that none of it is still within the uterus. Should the examination show that any considerable part or an accessory lobe is missing, it should be removed manually lest it cause bleeding.

A real postpartum hemorrhage is a serious condition demanding prompt, appropriate, and energetic treatment. Many will be avoided by careful, conservative obstetrics. To accomplish this, one should watch the parturient patient carefully. Keep her as comfortable as possible and thus conserve her strength. See that she is delivered with the minimum of trauma to the cervix and perineum. Insist that the uterus be held intelligently after delivery and that no attempt be made to express the placenta until it has separated.

ANNOUNCEMENT

POSTGRADUATE EXTENSION COURSES 1935-1936

The districts listed below will begin their courses this fall, the others are scheduled for the spring of 1936. You may obtain programs from your district chairman. Please see him for further details.

Meningitis and Cerebral Accidents (One
Session)

PEDIATRICS (Two Sessions)

November 20—Session 1

Abdominal Disease in Childhood, Medical and
Surgical Aspects

November 27—Session 2

The Neonatal State and its Diseases Medical and Surgical Aspects

PSYCHIATRY (One Session)

December 4—Management of Psychic States in the Care of General Diseases Especially Chronic Disorders.

Subpsychotic States.

KIDNEY AND BLADDER DISEASES—B (Two Sessions)

December 11—Session 1 (Medical)

Chronic Nephritis
Cardiorenal Disease.
The Use of Diuretics

December 18—Session 2 (Surgical)

Prostatism and Related Diseases
Cystitis and Pyelitis.

ROBERT B. BRIGHAM M.D., *Chairman*

MIDDLESEX EAST

(Meetings on Wednesdays at 4 00 P.M. at the McI rose Hospital Melrose, except the session on "Ophthalmology and Otolaryngology" on October 9 which will be held at the Bear Hill Golf Club Stoneham, at 1 30 P.M. Five sessions will be given this fall and the remaining sessions of the series in the spring.)

OPHTHALMOLOGY AND OTOLARYNGOLOGY (One Session.)

October 8

- The Major Hazards in Diagnosis of Disease of the Eye, Ear Nose and Throat as Seen in General Practice
- Special Treatment in Acute Medical and Traumatic Diseases of Eye. Emergencies arising in the Treatment of the Ear Nose and Throat.

ARTHRITIS (One Session.)

October 16

- Medical Care of Patient in the Home
- Orthopedic Treatment in Hospital and Aids in Home Treatment.

LUNG DISEASES (Two Sessions.)

October 23—Session 1

- Differential Diagnosis and Treatment of Lobar Pneumonia.

(b) The Surgical Problems of Empyema

October 30—Session 2

- Significance of Symptoms and Signs in Chronic Lung Disease Tuberculosis Bronchiectasis, etc.
- The Value of Surgery in Above Disease Problems.

PSYCHIATRY (One Session)

December 6—Management of Psychic States in the Care of General Diseases Especially Chronic Disorders.

Subpsychotic States.

JOSEPH H. FAY M.D. *Chairman*

MIDDLESEX SOUTH

(Meetings on Tuesdays at 4 15 P.M. at the Cambridge Hospital, Cambridge except the session on "Lung Diseases" on October 16 which will be held at the Middlesex County Sanatorium Waltham at the same hour)

LUNG DISEASES (Two Sessions)

October 15—Session 1

- Differential Diagnosis and Treatment of Lobar Pneumonia.
- The Surgical Problems of Empyema.

PSYCHIATRY (One Session)

October 23—Management of Psychic States in the Care of General Diseases Especially Chronic Disorders.
Subpsychotic States

KIDNEY AND BLADDER DISEASES—A (Two Sessions)

October 29—Session 1 (Medical)

Acute Nephritis—Etiology Diagnosis and Treatment.

Nephrosis and its Treatment.

November 5—Session 2 (Surgical)

Hematuria Its Significance in Surgical Diseases of Kidney and Bladder

ARTHRITIS (One Session.)

November 12

(a) Medical Care of Patient in the Home.

(b) Orthopedic Treatment in Hospital and Aids in Home Treatment.

CANCER. (Two Sessions)

November 19—Session 1.

Cancer of Breast and Uterus Sarcomas of Bone Lymphoma and Leukemia. Their Early Diagnosis.

Discussion of Life History of Cancer and Grades of Malignancy

November 26—Session 2

Cancer of Stomach Bowel and Genito-Urinary Tract.

Modern Care of Inoperable and the Incurable the Development of Improved Methods of Caring for these Cases with Less Pain and Discomfort with Minimum of Drug Therapy

DERMATOLOGY (One Session.)

December 3—Ten Common Skin Diseases—Diagnosis and Treatment.

- (1) Impetigo Contagiosa
- (2) Scabies
- (3) Acne Vulgaris
- (4) Psoriasis and Seborrheic Dermatitis
- (5) Epidermophytosis
- (6) Herpes Simplex and Zoster
- (7) Eczema
- (8) Erythema Multiforme
- (9) Verruca Vulgaris
- (10) Dermatitis Medicamentosa and Dermatitis Venenata

OPHTHALMOLOGY AND OTOLARYNGOLOGY (One Session.)

December 10

(a) The Major Hazards of Diagnosis of Diseases of the Eye, Ear Nose and Throat as Seen in General Practice.

(b) Special Treatment in Acute Medical and Traumatic Diseases of Eye Emergencies arising in the Treatment of the Ear Nose and Throat.

December 17—Neurological Aids in the Diagnosis and Treatment of Disease from the Medical Viewpoint. Problems of History and Examination with Special Reference to

- Neurosyphilis Multiple Sclerosis and Other Degenerative Conditions
- Diseases with Acute Onset Such as Meningitis and Cerebral Accidents. (One Session)

EDMUND H. ROBBINS, M.D. *Chairman*

NORFOLK SOUTH

(Meetings on Mondays at 8 30 P.M. at the Quincy City Hospital Quincy)

Dr Thomas C Quirk of Watertown, Associate Medical Examiner of the Seventh Middlesex District.

These appointments were confirmed by the Council as were the nominations of Dr Brickley and Dr O'Leary previously referred to in this Journal

DR. TRUESDALE TO ADDRESS THE ASSOCIATION FRANCAISE DE CHIRURGIE AT PARIS, FRANCE

Dr Philemon E Truesdale, of Fall River, has gone to France to give an address on "Operative Technique and Physiological Consequences of Diaphragmatic Hernia" before the Association Francaise de Chirurgie on, or about, October 10

DR. SPECTOR BECOMES THE SECRETARY TREASURER OF THE BOSTON MEDICAL HISTORY CLUB

Dr Benjamin Spector, Professor of Anatomy Tufts College Medical School, has been made Secretary-Treasurer of the Boston Medical History Club

RECENT DEATHS

MACDONALD—WILLIAM LEWIS MACDONALD, M.D. died in Malden, Massachusetts, September 24, 1935, at the home of his nephew, Dr W C MacDonald

Dr Macdonald was born July 29, 1834, at Cambridge, New Brunswick, the son of Alexander Black Macdonald and Janet Hendry Macdonald. He came to Boston in 1859 and studied dentistry for a time, probably in connection with attendance at the Harvard Medical School, receiving his M.D. degree in 1865. He served as district physician on the staff of the Boston Dispensary but, preferring dentistry, followed that professional work until 1910.

He joined the Massachusetts Medical Society in 1865 and retired in 1903. He was also a member of the Massachusetts Dental Society, the Harvard Medical Alumni Association, and was a Mason.

Since 1900 he had lived with his stepdaughter, Miss Grace Wilbur Conant, 95 Mt Vernon Street, Boston.

He was taken ill while on a visit to New Brunswick a short time before his death and was taken to Malden in an ambulance. His wife died in 1900. Dr Macdonald is survived by his stepdaughter, a stepson, Walter A. Conant of Temple, New Hampshire, and several nephews and nieces.

PFEIFFER—ALBERT PFEIFFER, M.D., died in the Memorial Hospital at Albany, N.Y., September 24, 1935, as the result of an automobile accident August 27.

Dr Pfeiffer was a member of the Massachusetts Medical Society from 1919 to 1925.

He was born in Franklinville, New Jersey, in 1882. During his residence in Massachusetts, he was active in public health work, and for the past ten years had been director of the Division of Social Hygiene of the New York State Department of Health.

He is survived by a daughter Miss Elizabeth Pfeiffer and three brothers, William Louis and Immanuel Pfeiffer all of Bedford Massachusetts

CLANCY—**WILLIAM HENRY CLANCY M.D.**, of 80 Otis Street, Cambridge Massachusetts died at his home, September 21 1935 He was born in 1865 and graduated from the New York University Medical College in 1886 He had maintained an active practice in Cambridge since 1891 and had served on the staff of the Cambridge Hospital and the Holy Ghost Hospital. He was physician to the Middlesex County Jail and Cambridge schools for many years previous to his retirement in August 1935

He was a Fellow of the Massachusetts Medical Society and the American Medical Association and held membership in the Cambridge School Board and the Boston Lodge of Elks

Dr Clancy is survived by his widow Mrs Mary Dwyer Clancy a son Paul E. Clancy and a daughter Mrs. Francis M. Greene of New York.

CARMODY—**BELLE SCOTT CARMODY M.D.**, of South Boston died September 23 1935 at the Boston City Hospital. She was born in 1888 at Taghkanic New York, and graduated from the Teachers College, Columbia University and from the College of Physicians and Surgeons in Boston in 1923

She was prominent in civic work in South Boston having been president of the Women's Club and chairman of the emergency relief committee

She had been active in legislative matters for several years, working for the protection of the interests of the Boston College of Physicians and Surgeons

She is survived by a son John G. Carmody and a brother George A. Scott. Her husband died several years ago

NOTICES

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday October 10 in the amphitheater of the Peter Bent Brigham Hospital Dr Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School will give a medical clinic. To it are cordially invited practitioners and medical students. These clinics will be repeated on Thursdays October to May

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12 staff rounds will be conducted by Dr Christian

INFANTS AND CHILDREN'S HOSPITALS CLINICAL CONFERENCE

A Clinical Conference by members of the staff of the Infants and Children's Hospitals will be held in the Amphitheatre of the Children's Hospital on Monday October 7 at 4 P.M.

BOSTON UNIVERSITY SCHOOL OF MEDICINE SURGICAL CLINIC AT THE BOSTON CITY HOSPITAL

Friday October 4 121 Cheever amphitheatre
Dr Robert C. Cochrane, Assistant Professor of Surgery Harvard Medical School will discuss "Thyroid Disease"

Physicians and medical students are invited

APPOINTMENT AS ASSISTANT SURGEON IN THE RESERVE CORPS OF THE U S PUBLIC HEALTH SERVICE

An examination for entrance into the Reserve Corps of the United States Public Health Service in the grade of Assistant Surgeon is hereby announced to be held November 18 1935 Applicants must not have passed their thirtieth birthday

Persons desiring permission to take this examination should make request to the Surgeon General U S Public Health Service, Washington D C., for the necessary blanks and other information

H. S. CUMMINGS Surgeon General

LECTURES BY DR. S. J. THANNHAUSER

Dr S. J. Thannhauser formerly Professor of Medicine and Director of the Clinic of the University of Freiburg Germany will give a course of clinical lectures during the coming academic year on Saturday mornings at 9 A.M. at the Boston Dispensary. The subjects for October and November are as follows

- October 5—Tuberculosis.
- October 19—Tuberculosis
- October 26—Nephritis
- November 2—Diabetes
- November 9—Diabetes
- November 16—Liver Disease.
- November 30—Peptic Ulcer

Practitioners in any part of New England are cordially invited. This course is made possible by a grant from the Bingham Associates Fund for the Advancement of Rural Medicine.

REMOVALS

HENRY W. HUDSON JR., M.D., announces the removal of his office to 1101 Beacon Street, Brookline Mass

WILLIAM F. DEWINE, M.D., announces the removal of his office from 5 Magnus Avenue, to 167 Elm Street Somerville Mass

WILLIAM M. SARTORE M.D., announces the removal of his offices to 500 Park Drive (off Beacon Street) Boston, Mass

NOTICES OF MEETINGS

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

Dear Doctor

About 200 out of a total membership of 850 Fellows of this District Society usually attend our meetings. Isn't it time that those of you who have become members of the Middlesex South District Medical Society during the past five years put in an appearance?

Do you know what the Medical Economic Situation is at present? Many of you do not know what laws have recently been passed which affect the physician.

If you attend the next meeting, chances are you will be much wiser in respect to our profession.

All this leads up to the following facts. This District Society will hold its next meeting at the Hotel Continental, Cambridge, on Wednesday, October 9, 1935, at noon. We meet to honor a most active member of our district, who is now the President of the Massachusetts Medical Society. Dr. Charles E. Mongan can and will tell you much of interest to yourself and the profession.

As usual all paid up members are guests of the Society at the luncheon. Internes of hospitals in this district are invited without charge. Members may obtain luncheon tickets for their friends from Dr. Edward Mellus, the Treasurer.

Many of you will attend the Postgraduate Extension Courses which begin on Tuesday, October 15.

If you know physicians who are not yet members of this Society, please instruct them to obtain applications from the Secretary. The next Censors' meeting takes place within a month.

We expect a record attendance.

SUMNER H. REMICK, *President*,
ALEXANDER A. LEVI, *Secretary*

*See page 693 for full particulars

THE CARNEY HOSPITAL

CLINICAL MEETING

October 7, 1935, 8 P.M.

The Diagnosis of Common Skin Diseases. Dr. William J. Macdonald. Lantern slides.

Diagnosis and Management of Pelvic Inflammation. Dr. Louis E. Phaneuf. Lantern slides.

Physicians and medical students invited.

THE SOUTH END MEDICAL CLUB

The ninth year of the South End Medical Club will begin on Tuesday, October 15, 1935, at 12 noon, at the Headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston. The speaker will be Austin W. Cheever, M.D., of the Syphilis Department of the Massachusetts General Hospital, and of the Skin Department of the Harvard Medical School. His subject will be "The Modern Treatment of Syphilis." All physicians are cordially invited to attend this meeting. Luncheon will be served at 1 o'clock.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, OCTOBER 7, 1935

Monday, October 7—

4 P.M. Clinical Conference, Children's Hospital Amphitheatre
*8 P.M. The Carney Hospital Clinical Meeting

Wednesday, October 9—

112 M. Clinico-Pathological Conference. Children's Hospital

Thursday, October 10—

*3 30 P.M. Medical Clinic at the Peter Bent Brigham Hospital
*5 P.M. Clinical Meeting—Faulkner Hospital

Saturday, October 12—

*10-12 Staff rounds at the Peter Bent Brigham Hospital

*Open to the medical profession
†Open to Fellows of the Massachusetts Medical Society

October 3—Faulkner Hospital Clinical Meeting at 5 P.M.

October 4—Boston University School of Medicine Surgical Clinic at the Boston City Hospital. See page 697.

October 5—November 23—Lectures by Dr. S. J. Thannhauser. See page 697.

October 6-20—Seventh Annual Training Course for Medical Residents at the Mayo Clinic. See page 441, issue of August 29.

October 7—Infants and Children's Hospitals Clinical Conference. See page 697.

October 7—Carney Hospital Clinical Meeting. See notice elsewhere on this page.

October 7-10—American Public Health Association will meet in Milwaukee, Wisconsin. For information address the American Public Health Association, 50 West 50th Street, New York City. See page 573, issue of September 19.

October 10—Medical Clinic at the Peter Bent Brigham Hospital. See page 697.

October 14-19—Inter-State Postgraduate Medical Association of North America. See page 549, issue of September 12.

October 15—South End Medical Club. See notice elsewhere on this page.

October 16—New England Physical Therapy Society. Detailed notice will appear in next week's issue.

October 21—November 2—1935 Graduate Fortnight of the New York Academy of Medicine. See page 898, issue of May 9.

October 28—November 1—The Twenty-Fifth Clinical Congress of the American College of Surgeons. See page 1066, issue of May 30.

DISTRICT MEDICAL SOCIETIES

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

October 9—See notice elsewhere on this page.

WORCESTER DISTRICT MEDICAL SOCIETY

October 9—Wednesday evening. Rutland State Sanatorium, Rutland, Mass. Program. 6 P.M. Dinner (complementary by State Sanatorium). 7 30 P.M. Scientific Program. 1. "X-Ray Diagnosis of Silicosis vs. Tuberculosis," Dr. David Zacks, Massachusetts Department of Public Health, Discussion, Dr. W. Irving Clark, Worcester, Mass. 2. "The Value of Blood Studies in the Selection of Cases for Thoracoplasty," Dr. Gullik Lindh Muller, Pathologist, Rutland State Sanatorium.

November 13—Wednesday evening. Grafton State Hospital, North Grafton, Mass. Dinner and scientific program. Subjects of program to be announced later.

December 11—Wednesday evening. St. Vincent Hospital, Worcester, Mass. Dinner and scientific program. Subjects of program to be announced later.

January 8, 1936—Wednesday evening. Worcester City Hospital, Worcester, Mass. Dinner and scientific program. Subjects of program to be announced later.

February 12, 1936—Wednesday evening. Worcester State Hospital, Worcester, Mass. Dinner and scientific program. Subjects of program to be announced later.

March 11, 1936—Wednesday evening. Memorial Hospital, Worcester, Mass. Dinner and scientific program. Subjects of program to be announced later.

April 8, 1936—Wednesday evening. Hahnemann Hospital, Worcester, Mass. Dinner and scientific program. Subjects of program to be announced later.

May 13, 1936—Wednesday afternoon and evening. Annual Meeting of Society. Time, place and details of program to be announced in an April issue of the Journal.

The Massachusetts Medical Society

SECTION OF OBSTETRICS AND GYNECOLOGY

Georgian Room, Hotel Statler, Boston,

June 3, 1935, 2 P.M.

PRESIDING

Dr Thomas Almy Fall River Chairman.

Dr Charles J Kickham Brookline Secretary

CHAIRMAN ALMY The Section will please come to order. The first business of the meeting is the election of officers for next year. I will ask Dr Bristol Chairman of the Nominating Committee to report.

DR. BRISTOL Charles J Kickham as Chairman
R. S Titus as Secretary

CHAIRMAN ALMY Are there any other nominations? There being no other nominations gentlemen what is your pleasure?

A MEMBER I move that the Secretary cast one ballot.

CHAIRMAN ALMY It is moved that the Secretary cast one ballot. The Chairman will do it, as the Secretary is modest. All those in favor say Aye those opposed No. Dr Kickham is elected Chairman and Dr Raymond Titus is elected Secretary of this Section for the next year.

I would like to call attention to the notice that is on the top of the piano as we have no loud speaker. Anyone who discusses will please come forward so that all may hear him.

Dr Mongan is unavoidably delayed so Dr Davis has agreed to read the first paper on the program. The title of his paper is "Diagnosis and Treatment of Lesions of the Cervix Uteri Illustrated with Lantern Slides." We are very fortunate to have Dr Davis with us. He has come from Milwaukee to speak to us on a subject on which he has spent a good deal of time and upon which he is an authority. Dr Davis.

LESIONS OF THE CERVIX UTERI—DIAGNOSIS AND TREATMENT*

BY CURI HENRY DAVIS, M.D.†

THE subject of cervical lesions is so large that little more than a summary of the more important conditions can be presented in a short paper. Unfortunately it is practically impossible to compile statistics which will give a reasonably accurate idea regarding the age incidence or frequency of various lesions. Neither can we speak dogmatically regarding the end results of treatment since this would require following every patient from the time of treatment to the time of her death, a requirement which is obviously impossible. Investigation of the few statistics which have been published indicate that they are not based on accurate investigative methods and that they should be considered as suggestive rather than proved results.

Endocervicitis Infection of the cervical canal was not recognized as a clinical entity until Stroganoff and Winter in 1896 demonstrated that bacteria are not normally found above the external os. Seven years earlier Winter had determined that the endometrium normally is free from bacteria. Arthur Curtis, in

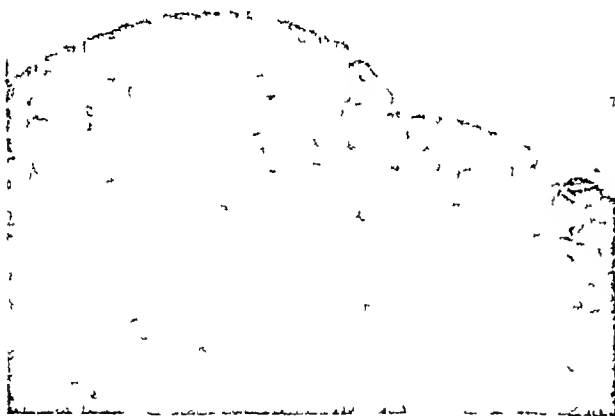

1918, confirmed Winter's observations regarding the endometrium and added to the evidence showing that the cervical glands are prone to become chronically infected. Laura Moench in 1924 reported that organisms grown from chronically infected cervical glands of patients suffering from chronic arthritis were culturally identical with those commonly found in other chronic foci of infection in arthritis patients and that these organisms when injected according to the technique of Rosenow would produce joint lesions in rabbits. My own clinical experience indicates that whenever streptococci, especially the viridans type, can be grown from the cervix of a patient with arthritis, canterization of the cervical glands will be followed by a temporary exacerbation of symptoms. Cleaning up the cervical infection usually is followed by clinical improvement and in a few cases where other foci had been removed previously the degree of relief was beyond expectation.

It may be impossible to prove a clinical connection between chronically infected cervical glands and adnexal disease yet the relief of symptoms following correction of cervical infections indicates that a definite relationship must exist. Among the symptoms relieved after adequate treatment are dysmenorrhea, dyspareunia,

*Read at the Annual Meeting of the Massachusetts Medical Society, Section of Obstetrics and Gynecology, June 3, 1935.
†Dr. C. H. Davis—Clinical Professor and Director of Department of Obstetrics and Gynecology, Marquette University School of Medicine, Milwaukee, Wis. For record and address of author see "This Week's Issue" page 129.

reuma, pelvic tenderness, pelvic pain, lumbosacral backache, menorrhagia, metrorrhagia, and sterility

Erosions of the Cervix There is much confusion in our literature due to the differences of opinion regarding ectropion and erosions. Contrary to the teaching in some schools, I am completely in accord with Curtis who reports that careful microscopic study of an adequate number of sections from "eroded" cervixes shows that a large percentage are devoid in some areas of an epithelial covering, the surface often being composed of granulation tissue infiltrated with polynuclear leukocytes and extensively invaded with bacteria. There may be a variety of causes but the most important is the irritating discharge from a cervical infection. Correction of the endocervicitis should be followed by epithelialization of the denuded areas. However, in some cases the granulation tissue must be cauterized before proper healing can be secured.

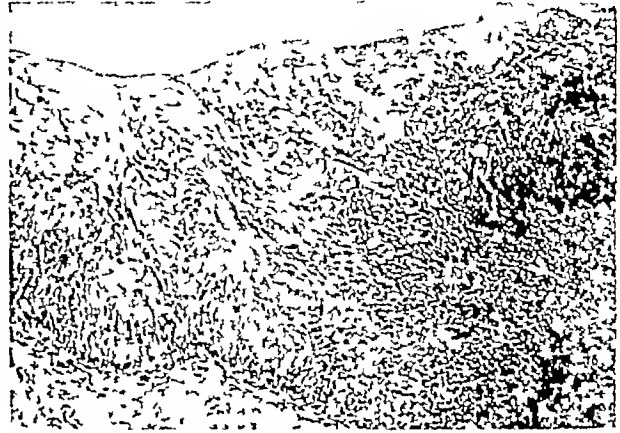

Small exophytic carcinoma diagnosed during a colposcopic examination by Hinselmann. A high amputation of the cervix was performed as the patient was young and desired children.

Ectropion of the Cervix Colposcopic examinations of the cervix uteri indicate that many women normally have gland openings at some distance from the external os. These should be distinguished from ectropion of the cervical glands associated with lacerations or resulting from an actual eversion or growing out of the glands. A patient may have an erosion superimposed upon an ectropion. Hinselmann recognizes a congenital type of ectropion in his classification of conditions diagnosed with the colposcope, and he does not consider it important so far as cancer is concerned. However, everted glands tend to become infected and the patient may have all of the symptoms associated with endocervicitis.

Lacerations of the Cervix Childbirth is responsible for most lacerations although some may follow various forms of instrumentation. In general, tears resulting from hasty or improper dilatation do not show externally al-

though they may cause serious bleeding. As previously stated lacerations result in an eversion of the endocervical glandular tissue which becomes infected. Many of the symptoms associated with old lacerations are those of the associated infection. Most writers assume that lacerations increase the possibility of cervical cancer, but this must be considered a sequela of the chronic irritation of the secondary infec-

Leukoplakia (Matrix) Grade IVb. Carcinoid epithelium with many pathologic mitoses and proliferation into the connective tissue.

tion. It is undoubtedly true that cervical lacerations increase the risk of abortion, but here again it is possible that the chronic cervical infection plays an important rôle.

Stricture of the Cervix Cervical stricture may follow various forms of trauma, especially that of infection, cauterization, coagulation, conization, chemical cauterization, operations such as amputations or curettage of the cervical glands, radium therapy and occasionally after trauma of complicated labor. While this condition is relatively common, it is preventable following the various types of therapy of endocervicitis provided the patient has adequate office treatment until healing is complete. The cervical canal must be kept open.

Syphilis of the Cervix Syphilitic lesions of the cervix are rarely observed even by gynecologists of large experience. However, the chancre may be located there and undoubtedly is more often than we realize. Gellhorn, who has written extensively on this subject, reports that the secondary lesions frequently may be found if the syphilitic woman is followed closely, and that the tertiary lesions tend to produce hypertrophy with subsequent necrosis. The gynecologist must realize that gummatous lesions may involve the cervix as well as other organs and be on the lookout for them in syphilitic patients. Syphilis of the cervix and cancer of the cervix may coexist.

Tuberculosis of the Cervix Cervical tuberculosis is a rather rare condition as evidenced by the report of Norris who found only four

cases among seventy four specimens of genital tuberculosis in his laboratory at the University of Pennsylvania. This condition usually is associated with and probably secondary to tuberculosis of the uterine cavity. It has been suggested that it might be primary as a result of a tuberculous man moistening a condom with spurtum. The finding of tubercle bacilli is sufficient to make the diagnosis, but if there is any doubt tissue should be secured for microscopic examination.

Streptothrix Infection of the Cervix It has been assumed that ray fungus (actinomyces) infections of the genital tract are quite rare but recent observations at the Kingston Avenue Hospital, New York, by Barringer and Thomson indicate that this condition may be responsible for many unexplained cases of ulcerative pathology of the genital tract. In a series of eighty nine cases diagnosed clinically as gonorrhea, forty nine patients were found by cultural methods to have the streptothrix organisms. The pathological process in the more severe infections is inflammation characterized by a tenacious purulent discharge which is sometimes membranous in type and accompanied by necrosis with considerable loss of tissue (Barringer). These observers are preparing a new report which will be published shortly.

Cancer of the Cervix There are a few phases of the cancer problem regarding which clinicians are agreed. (1) Cancer does not develop in perfectly normal tissue. (2) Various forms of chronic irritation constitute predisposing factors which favor the development of cancer. (3) Every cancer in its earliest stage is a localized microscopic lesion. (4) Most cancers can be cured if diagnosed early and adequately treated.

Notwithstanding the campaigns of education carried out by various organizations during the past decade or two, it is still true that most cancers of the cervix are not seen by a physician until the patient has the symptoms of a late lesion. As a result only a small percentage of permanent cures is obtained. It is obvious that early diagnosis can be assured to any great extent only when women have periodic physical examinations. Furthermore, even though every woman did have a regular examination once or twice each year, the possibility of recognizing a very early carcinoma by palpation or the usual type of inspection is questionable unless the lesion has reached the size of a small pea. Recognition of this fact led Hinselmann to develop his colposcope by means of which a small carcinomatous ulcer, too small to be seen with the unaided eye is enlarged to a size which makes its recognition possible. The use of this instrument combined with the Schiller test, which is useful in selecting biopsy material should enable us to make an earlier diag-

nosis of cervical carcinoma than was formerly possible in the examining room. Hinselmann in a recent letter informed me that he now has "136 cases of beginning cancer detected only by the colposcope." Cancer is an easily curable disease if diagnosed and treated while the lesion still is microscopic.

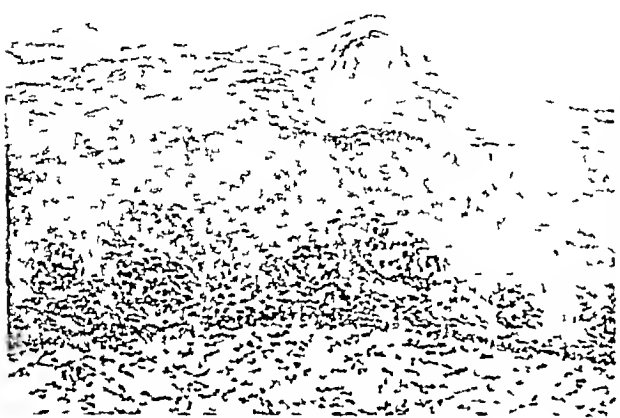

Leukoplakia (Matrix) Grade II. This is from a very small lesion area. The growth in this case was exophytic. Colposcopic diagnosis—leukoplakia.

Diagnosis of Cervical Lesions Several of the more common conditions involving the cervix have been discussed briefly in the first part of this paper. Diagnosis of the actual lesion may depend on palpation, inspection through the speculum with the unaided eye and the colposcope, wet and stained smears, cultures, blood tests for syphilis, and a study of biopsy material. Only with experience may a clinician decide which procedure may be omitted during the examination of any patient. A large portion of serious mistakes result from failure of clinicians to use even the simple easily accomplished office procedures. It is distressing to find that many of our ablest internists commonly neglect inspection of the cervix when they make a "thorough" examination of a woman patient. Every gynecologist has seen a considerable number of women who have been under more or less constant supervision of a family physician or a medical specialist during the time when a cancer of the cervix was passing from a curable to a hopeless condition. It is regrettable that we still see far advanced cancer of the cervix in women who have had a subtotal hysterectomy a few months previously for fibroids or some other pelvic condition without any record to show that the cervix had ever been examined prior to the abdominal operation. (Points in diagnosis were shown in lantern slides.)

Diagnosis with the Colposcope Considerable experience with the colposcope is necessary before one may use it satisfactorily in the diagnosis of cervical lesions. First one must obtain an accurate knowledge of the varied but essentially normal physiologic structure of the cervix uteri. This accomplished variations from the normal may be recognized and diagnosed quite accurately. Hinselmann is convinced that with

the colposcope it should be possible to recognize an exophytic carcinomatous proliferation even if only one papilla should be involved, but such a finding would be exceedingly rare since more than one usually is involved. An endophytic carcinoma is recognized with greater difficulty since the growth is inward and the diagnosis must depend on the size of the overlying ulcer and the type of the secretion. Larger ulcers have a very characteristic appearance showing areas of necrosis, yellowish nests of cancer cells, and blood vessels running longitudinally, but it is almost impossible with the colposcope to differentiate a true erosion and a carcinomatous ulcer. It must be appreciated

Leukoplakia (Matrix) Grade I. Atypical hornified epithelium (colposcopic diagnosis—leukoplakia).

also that some endophytic carcinomas may still be covered with the original epithelium from which the growth originated so that they will not appear as ulcers at the time of an examination. With the usual type of inspection it may be impossible to differentiate carcinomatous epithelium and the surrounding epithelium, but with the colposcope the diseased area stands out, and should be recognized easily.

Several practical problems of considerable importance may be noted when considering the colposcopic picture of leukoplakias. (1) It is not possible to correlate the colposcopic appearance with the microscopic findings. (2) Definitely malignant leukoplakias may have the same colposcopic appearance as those which are microscopically benign. (3) Biopsy material from a cervix with many areas of leukoplakia may not permit a definite diagnosis since the excised area and the rest of the cervix may have a very different histologic structure. Hinselmann is undoubtedly correct in stating that one may rely on a microscopic negative diagnosis only when serial sections of the entire leukoplakia or the entire cervix have been studied. (4) The gynecologist should attempt to diagnose Hinselmann's matrix areas since their removal by amputation of the cervix or their destruction with the nasal type cautery or surgical diathermy

may cure an early carcinoma. (5) Early diagnosis and eradication of diseased areas is the only method available for the prophylaxis of carcinoma of the lower genital tract of women.

Unless one has studied serial sections of a large number of cervixes removed by amputation or hysterectomy it is not probable that some of the tissue changes described by Hinselmann will have been observed. He recognizes pre-matrix change of two types and four grades of matrix change before finding easily recognized cancer. His studies suggest that preleukoplakia and developing leukoplakia may be reversible so that if the underlying cause for the condition is removed the mucous membrane may heal and assume a normal appearance. However, it is apparent that a fully developed leukoplakia or matrix area cannot return to a normal state, hence removal or destruction is necessary. The accompanying photomicrographs illustrate Hinselmann's classification.

The types of treatment which may be used for various cervical lesions are described quite adequately in various works on gynecology, and no attempt need be made to review them in detail here.

Leukoplakia (Matrix) Grade III. Carcinoid epithelium with many pathologic mitoses. Colposcopic diagnosis—leukoplakia.

American gynecologists for some years have emphasized the importance of diagnosing and correcting by appropriate therapy lacerations, ectropion, erosions, polyps, and cysts of the cervix uteri. Personal observations indicate that European gynecologists are inclined to employ a surgical procedure for many conditions which we would treat with the nasal type electric cautery, Cherry's coagulation, or Hyams' conization. At the same time they leave untreated many abnormal cervical conditions which we would correct in the office with one of the previously mentioned procedures.

There may be individual and sectional differences of opinion regarding various corrective forms of treatment but most of us will agree that all cervical lesions should be kept under observation and treated by some method until

satisfactory healing has been secured. Every statistical study, even when we make a considerable allowance for possible errors, indicates that careful prophylactic treatment of cervical lesions is a satisfactory means of preventing the later development of cervical cancer. It is highly probable that each of us who has used the nasal type electric cauterizer or surgical diathermy for some years has destroyed a few microscopic

Leukoplakia (Matrix) Grade II. Hornified atypical epithelium proliferating into the connective tissue. Colposcopic diagnosis—leukoplakia.

cancers, thereby curing such women from cancer just as effectively as if they had had a radical treatment with surgery or irradiation.

It has been suggested by some that the general use of the colposcope for cervical diagnosis might lead to a considerable amount of unnecessary surgery. Hinselmann has a patient who had an early cancer of the cervix treated by amputation of the cervix who has gone three years without any further evidence of trouble which shows that there is a great difference between the treatment of an early microscopic cancer and one which is well developed. Our use of the cervical type electric cauterizer or surgical diathermy probably would have been as effective as the amputation. During the past year I have examined with the colposcope a large number of cervixes which had been treated with the nasal type cauterizer or surgical diathermy during the past ten years. The results observed were very satisfactory; the colposcopic appearance of the cervix being normal in most instances. Therefore, it would appear that we are justified in continuing to treat in the office the majority of patients who have minor lacerations, erosions, and polyps with the nasal type cauterizer or surgical diathermy. The Hynns' conization has a definite advantage over the cauterizer and Cherry's bipolar coagulation since the tissue removed is available for microscopic examination. Surgical removal of the cervix and hysterectomy should be reserved for older women and those who have other indications for surgery. Early diagnosis and treatment of cervical lesions is an effective means of

preventing cervical cancer. Early diagnosis of developing cancer and adequate treatment by means of irradiation or radical surgery will greatly increase the number of permanent cures.

DISCUSSION

CHAIRMAN ALMY Dr Hutchins will open the discussion.

DR. HENRY T. HUTCHINS Boston, Mass. *Mr. Chairman and Members of the Section*—

It is difficult to see how we can do otherwise than agree with Dr. Davis' sane and comprehensive résumé of the many lesions of the cervix uteri. I feel that we concur with him. This paper has forcibly brought to our attention what seems to me to be a fact that is too little recognized.

Cervix uteri is a distinct organ in itself apart from its being connected with the uterus. In discussing lesions of the cervix alone Dr. Davis has focused our attention on this fact, namely that we must consider the diseases of this organ as entities apart from the uterus itself just as much as we must consider lesions of the stomach and rectum apart from the whole intestinal tract. Although connected with the fundus uteri the cervix uteri is a distinct organ physiologically and histologically. It is the inlet and outlet of the uterine canal and functions only as such. It is sharply differentiated from the fundus at the level of the internal os. Its histological picture is entirely different from the fundus as to its glands, muscle and fibrous connective tissue. It, therefore, deserves consideration from the surgeon as a distinct organ of the body and as it is subject to diseases peculiar to itself it must be examined and treated with more thought and care than it has been in the past.

We are apt to consider the cervix as an internal organ and therefore more or less inaccessible whereas, the opposite is true. The cervix is an external organ and just as accessible as the tongue or the tonsils. It can be examined under the eye and finger and can be treated easily. Dr. Davis has told us of many procedures which can be carried out as simple office procedures, and if we will only take the trouble to regard this organ as a source of real disease—e.g. cancer for one—we can prevent a great deal of systemic disability and of course we shall even save a good many lives.

I want to make the strongest possible plea for the examination of the cervix by physicians and especially by insurance examiners and the so-called Life Extension Institutes where yearly check-ups are supposed to be made. I have recently seen a case of inoperable pelvic disease where the patient had for fourteen years conscientiously gone for a complete physical examination every year and yet not once in the fourteen years was a pelvic examination made. The trouble could and should have been detected in time to have saved her life and the tonsit was not the patient's.

What can be done today by way of inspection with the colposcope treatment by electric cauterizer and diagnosis has been only too clearly demonstrated in the paper to which we have just listened.

We must remember then that the cervix as an organ is a distinct entity and subject to its own diseases which unfortunately do not always give early symptoms and therefore should be observed and treated as a routine part of every physical examination in woman.

These remarks may seem to you somewhat trite but when one sees as I have in the past month a case of inoperable carcinoma of the cervix develop under the care of a physician living not in the rural districts but in a city of 100,000 inhabitants

to whom the patient went for advice for over fourteen months and no pelvic examination was made, one cannot help but feel that failure to make a pelvic examination with inspection of the cervix, comes dangerously close to medical malpractice.

Dr. Davis, in his paper and in his lantern slides, has shown us the points in the diagnosis of early carcinoma of the cervix, and these remarks of mine will serve only to emphasize a statement which he makes in his paper where he says, "It is distressing to find that many of our ablest internists commonly neglect inspection of the cervix when they make a thorough examination of a woman patient. Every gynecologist has seen a considerable number of women who have been under more or less constant supervision of a family physician or a medical specialist during the time that a cancer of the cervix was passing from a curable to a hopeless condition—without any record to show that the cervix had ever been examined—". The use of the colposcope in the hands of the specialist is new, and will undoubtedly prove of value in determining early cervical lesions, but if we can bring about the inspection of the cervix by the eye alone as a more general procedure throughout the profession, many more hopeless cases will be eliminated.

I wish Dr. Davis could present this paper before the Medical Section of this Society as well as before our Section, in order that the necessity of routine examinations of the cervix, and the ease with which cervical examinations can be made, might more clearly be brought to the attention of the internists. It is perhaps a little more bother to make a pelvic inspection than to take a look down a patient's throat, but the actual examination with a bivalve speculum is just as simple. The colposcope is not necessary for the internist. The untrained eye can detect early abnormalities and then the patient can be referred to the gynecologist for differential diagnosis and early treatment. Just because a patient has no pelvic symptoms, which is frequently the case in early carcinoma of the cervix, is no excuse for the omission of inspection of the cervix during routine physical examinations.

CHAIRMAN ALMY: Dr. George Van S. Smith of Brookline will continue the discussion.

DR. SMITH: *Mr. Chairman, and Ladies and Gentlemen—*

Doctor Davis' comprehensive survey leaves little to consider except by way of confirmation.

At the Free Hospital for Women, tuberculosis of the vaginal portion of the cervix has never been recognized. Of ninety-seven cases of pelvic tuberculosis, high endocervical involvement was found once. Syphilis of the cervix has not been seen.

The recent discovery of a chemical relationship between estrogenic substances and those producing experimental malignant disease suggests that hormonal influence be added to trauma, inflammation and chronic irritation as a possible factor in the etiology of cervical cancer, especially since over 90 per cent of patients with this disease give a history of pregnancy, which brings about tremendous changes in the estrogenic hormones.

The importance of conscientious attention to the cervix during any gynecological operation cannot be overstressed. Five of our own cases were found to have cancer of the cervix five months to four years following supravaginal hysterectomy performed eight to twenty years ago without careful examination and biopsy of the cervix.

We are constantly confronted with the problem of whether to treat diseased but symptomless cervixes. Specimens are taken for biopsy on the slightest suspicion, but, unless early cancer is actually present, the only indication for treatment is that it

may prevent later trouble. The taking of specimens for biopsy introduces more problems. First, should we be guided in removing tissue by the Schiller test and the colposcope? Despite a fairly extensive use of the iodine test during the past three years and the employment of the colposcope for one year, it so happens that our ten diagnoses of early cancer during this period have been made without these aids. Furthermore, I have been able to find only one instance in which tissue was taken from a non-malignant area when cancer was almost certainly present somewhere else in the cervix. The Schiller test and the colposcope are helpful but not necessary.

The next problem is that of pathological diagnosis. All those experienced in cervical pathology tend to agree that the so-called "precancerous" picture need not cause alarm, for there is no evidence that this is, or necessarily becomes, malignant. The real difficulty is that pathologists do not agree on what constitutes the picture of true early cancer. The criteria of Schiller and Hinselmann are not entirely accepted. I now have sections from twenty-three cervixes which I believe show early carcinoma. Of fourteen of them submitted for pathological consultation, only one was considered malignant. A second was thought to contain cancer by two out of five consultants. The patients from whom three other sections were submitted, however, had advanced cancer four to six years after biopsy. Of the other twenty patients, one was treated too late, the rest were treated and are well up to eight years with the exception of one who had endometriosis and reacted severely to irradiation.

Finally, does treatment of diseased cervixes prevent later trouble? From the point of view of inflammation and chronic irritation, we know that in general it does. That it may lower the incidence of later cancer is almost impossible to prove. Dr. S. S. Woolston traced 1014 cases of trachelorrhaphy from ten to over thirty years and found that fourteen developed later cancer of the cervix, that five more probably developed it and that four others may have died of it—an incidence at the highest of 2.3 per cent. Four of these patients had had pregnancies after trachelorrhaphy. We have traced 591 cases of cauterization of the cervix five to over twenty years, 37 per cent of them ten to over twenty years. Four hundred and seventy-two had had pregnancies before cauterization. One of these died six years later, cancer of the cervix being stated as the cause. Two others had proved cervical cancer six and six and one-half years after cauterization. The highest incidence we can make for this group is 0.65 per cent. It is impossible to obtain an accurate control figure. Dr. Woolston found statistics indicating that about 2.95 per cent of all women who reach the age of thirty-five in this country die of carcinoma of the cervix. Dr. J. W. Schereschewsky of the United States Public Health Service, who has very generously tried to supply me with a control figure, considers 2.95 per cent too high and calculates an incidence of about 1.6 per cent as being more nearly correct for the country and 2 per cent for Massachusetts. Taking these percentages for what they are worth and allowing for the fact that the percentages for the incidence of cancer after treatment cannot be correct until all cases have been followed until death, it would appear that trachelorrhaphy has little if any prophylactic value and cauterization may have very definite preventive effect. In extenuation there are two considerations to be mentioned. First, the treated cervixes undoubtedly had more marked lesions and probably would have been even more prone to malignant change without treatment. Secondly, the figures I have submitted for the treated cases are based entirely on those which had had pregnancies, whereas the control percentages were calculated for both

nulliparous and parous women. The evidence indicates that treatment of diseased cervixes is not ill-advised even when they are symptomless.

CHAIRMAN ALMY The paper is now open for discussion.

DR. BENEDICT F. BOLAND Boston, Mass. I would like to add my appreciation of the very thorough and well-written paper which Dr. Davis has delivered this afternoon. His lantern slides have clarified many details that are essential in the conduct of this work. In his paper and slides he has dealt considerably with the nasal point cautery and has made some mention of the surgical high frequency types of currents. In view of his remarks and experiences in the use of these modalities I would like to ask the doctor what percentage of good results he has obtained with the nasal tip type of cautery as compared with the high frequency surgical diathermy type of currents, and also whether he has had any experience in the use of these modalities in the treatment of chronic infections especially of the Neisserian type.

From my own experiences I appreciate that none of these various methods of approach are a panacea in every case. However in an analysis of five hundred cases which I have performed during the past five years, on the services with which I am associated at the Boston City Hospital, St. Elizabeth's Hospital, and at the Massachusetts General Hospital, and in private practice, I am convinced that excellent or satisfactory results can be obtained in 65 to 75 per cent of these types of cases. As no two cervixes are alike the selection of the case to which these modalities are to be applied and judgment in application are essential if satisfactory results are to be obtained. In the chronic type good results have been achieved in those cases that were free of pelvic tenderness or masses. These measures are contraindicated in the acute infections or pelvic inflammatory type lest extension of the parametric infection or peritonitis be produced. Gentleness is required as the operator can encounter severe difficulty unless acquainted with the use and application of these methods.

In these local hospitals the Cherry Remington and Hyams' methods have been used clinically. Not being one hundred per cent satisfied with these methods experimental work has been performed on dogs in the Research Laboratory of the Boston City Hospital in collaboration with Dr. Stephen J. Mad dock. Our aim has been to determine the amount of tissue destruction that resulted in the utilization of each of these methods. Both clinically and experimentally the Hyams' type has proved to be the best method. The Cherry method as the doctor has stated has limited application and has not worked satisfactorily in the multiparous type of cervix. The Remington method has produced good results in selected cases.

I would like to know, Doctor, what your end results

have been in a comparison of these methods? I thank you.

CHAIRMAN ALMY Do you wish to answer that now, Doctor?

DR. DAVIS I cannot answer from the point of view of percentages. I started the nasal type of cautery some fifteen years ago following Dr. Dickinson's first paper and my largest experience is some place between twelve and fifteen hundred patients treated with the very fine bladed cautery in contrast to the heavy blade of the nasal operating room cautery or the more destructive post cautery. As you could see from the colored plate on the screen, we make our linear incisions some distance apart, and do not get the type of destruction which is obtained with a heavy instrument. My experience with the Cherry cautery has been that it is a poor instrument for the lacerated cervix. I personally am afraid to remove the speculum and let the cervix come down for fear I will do too much damage. As a result, in the few cases where I have used it I have usually destroyed the point by sparking it across and burning an area through the bakelite.

More and more, as I become experienced with it I am inclined to use the Hyams' coagulation.

Now in regard to the chronic gonorrheal infection of the cervix I believe you can get a good result with either the Cherry or the Hyams' method. I think probably the Hyams' is somewhat the safer method in that you do not get the amount of blocking and holding back of secretions following its use that you do when you use either the cautery or the Cherry coagulation.

You will recall that in the *Journal of the American Medical Association* a surgeon in Milwaukee reported two patients whom he had seen with very severe complications following the use of surgical diathermy. The statement was not clear and I have not had the opportunity to investigate those cases. Of course everyone who has written on the use of these treatments has emphasized the fact that you must not use them except in chronic types of infection. They are dangerous with either acute or subacute cases but are relatively safe in the chronic cases. I believe that they should be used more widely over the country than they have been in the past.

CHAIRMAN ALMY I am sure we all feel that we are greatly indebted to Dr. Davis for coming here and giving us this splendid paper.

The next paper is by Dr. Charles E. Mongan. His paper is on "Maternal Mortality—A Demand for Fairness."

DR. CHARLES E. MONGAN Mr. Chairman and Gentlemen—

I have taken the liberty of changing the title of this paper without consultation with the Chairman of the Section. The title was "Maternal Mortality—A Demand for Fairness." The title now is "Changes in Maternal Mortality and their Significance."

CHANGES IN MATERNAL MORTALITY AND THEIR SIGNIFICANCE*

BY CHARLES E. MONGAN, M.D.†

I. INTRODUCTION

THE best approach to the problem of maternal mortality seems to be from the side of statistics. Although they lie somewhat aside from medical problems their conclusions, taken over

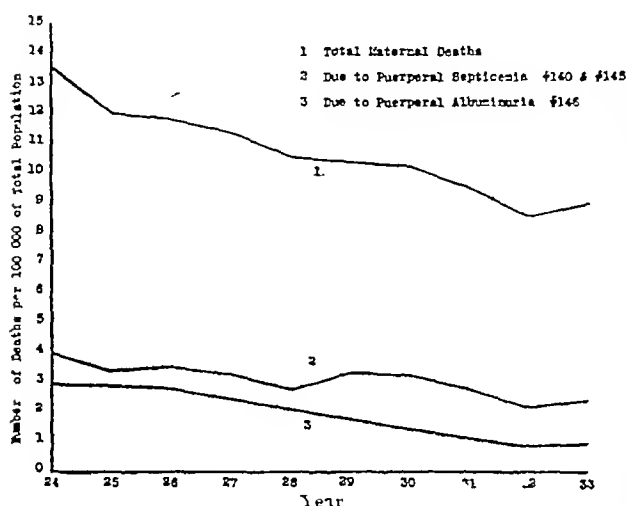

a period of years, form a measure of medical progress. In some instances they can give a direct medical clue, amounting almost to a diagnosis. A close study of the records shows that very creditable work has already been accomplished. An analysis of the structure of the death rate shows which causes of death have yielded to our efforts and which are still a challenge. The distribution of the death rate

*Read at the Annual Meeting of the Massachusetts Medical Society, Section of Obstetrics and Gynecology, June 3, 1935.
†Mongan, Charles E.—Visiting Surgeon, Holy Ghost Hospital for Incurables and Somerville Hospital Senior Staff. For record and address of author see "This Week" Issue—page 729.

throughout the State indicates that many factors are at work. On the whole the results already obtained entitle us to a reasoned optimism for the future.

The following study has been based on official Massachusetts reports. Some of the data have been compiled and calculated by the Department of the Secretary of State. Other parts have been calculated by the author. The figures

MATERNAL DEATHS OVER A PERIOD OF YEARS

have been collected by the State in accordance with the law and with the international conventions. They are believed to be very reliable, which is a tribute to the conscientiousness of the reporting physician.

OBSERVATIONS

A decrease in the total mortality is readily discernible. It is therefore interesting to see its amount, to study its causes, and to estimate its future. According to the data the rate has declined from 12.5 to 9.0 per 100,000 in 1933 (See table 1). This is a decline of about twenty-five per cent in the death rate. However, to gain a better insight into the processes at work, it is desirable to analyze the total rate.

Consider that part of the death rate due to septic abortions and puerperal septicemia (See table 2). These are causes No 140 and No 145 respectively of the International List. A calculation of the figures for 1931, 1932 and 1933 indicates that cause No 140 (septic abortions) seems practically constant at twenty per cent of the sum of No 140 and No 145. Over a ten-year period the death rate due to No 140 and No 145 has fluctuated considerably. It is now slightly lower than it was.

Now let us consider the part of the rate due to puerperal albuminuria (see table 3). This rate has shown a constant and persistent decrease until it is now a small contributing factor. Then the tables refer to the changes of the death rate over a period of years. To gain more information regarding the forces at work, it is well to study the structure of the death rate for a given year, say 1933 (See table 4).

We can arrange the causes of death in the order of the number of deaths they have caused.

TABLE 1

TOTAL MATERNAL DEATHS IN MASSACHUSETTS OVER A PERIOD OF YEARS

Year	1923	1924	1925	1926	1927	1928	1929	1930	1931	1932	1933
Number	498	544	501	501	486	456	453	438	408	369	389
Rate	12.5	13.6	12.1	11.9	11.4	10.5	10.4	10.3	9.5	8.6	9.0

Number refers to the sum of all deaths from causes No 140 to No 150 of the International List calculated on the basis of 100,000 of the population.

TABLE 2

DEATHS FROM PUERPERAL SEPTICEMIA

Year	1923	1924	1925	1926	1927	1928	1929	1930	1931	1932	1933
Number	128	161	140	150	141	123	147	141	119	96	103
Rate	3.2	4.0	3.4	3.6	3.3	2.8	3.4	3.3	2.8	2.2	2.4

Deaths due to the sum of causes No 140 and No 145 of the International List calculated per 100,000 of the population. Cause No 140 is septic abortion. Cause No 145 is puerperal septicemia. Deaths due to cause No 140 run twenty per cent of those due to the sum of No 140 and No 145.

TABLE 3

DEATHS FROM PUERPERAL ALBUMINURIA, BEING CAUSE NO 146 OF THE INTERNATIONAL LIST

Year	1923	1926	1931	1932	1933	1934	1935 ($\frac{1}{4}$)
Number	130	120	52	35	41	29	5
Rate	3.0	2.8	1.2	80	95	67	46

The rate is calculated for 100,000 of the total population.

TABLE 4

DISTRIBUTION OF MATERNAL DEATHS AMONG THE
VARIOUS CAUSES FOR 1933

Int List Num ber	To- tal Deaths	Rate per 100 000	Per Cent	Cause
140	19	0.43	4.9	Septic Abortions
141	18	0.37	4.1	Abortions Without Men- tion of Condition
142	20	0.45	5.1	Ectopic Gestation
143	1	0.02	0.26	Accidents of Childbirth
144	56	1.30	14.3	Puerperal Hemorrhages
145	84	1.94	21.6	Puerperal Septicemia
146	41	0.95	10.5	Puerperal Albuminuria
147	25	0.60	6.7	Other Toxemias of Preg- nancy
148	55	1.27	14.1*	Puerperal Phlegmasia etc. (53 were Embol- ism and Thromboses)
149	67	1.55	17.2	Other Accidents (70 were Cesareans)
150	4	0.09	1.0	Unclassified
389		9.00	100%	

*Cause No 148 of the International list includes Puerperal Phlegmasia Alba Dolens, Embolus Thrombosis Sudden Death not specified as septic

TABLE 5

DISTRIBUTION OF MATERNAL DEATHS THROUGHOUT
THE STATE

City	Popula- tion	P Sept	Oth ers	Rate P S	Oth ers
Attleboro	21 769	0	1	0	4.5
Cambridge	112 543	4	16	8.4	14.0
Dedham	15 185	0	0	0	0
Everett	45 424	0	4	0	8.2
Fitchburg	40 692	0	3	0	7.4

Waltham	39,247	1	0	2.6	0
Woburn	19 434	0	0	0	0

(1) Puerperal Septicemia, No 145 with twenty-two per cent, (2) Other accidents, No 149 with seventeen per cent, (3) Puerperal Hemorrhages No 144 with fourteen per cent (4) Puerperal Phlegmasia, No 148 with fourteen per cent, and (5) Puerperal Albuminuria with eleven per cent. One third of all deaths in class No 149, or nearly five per cent of all maternal deaths, were associated with cesarean operations. On the other hand practically all deaths charged to No 148 are due to embolism.

In table 5 the distribution of deaths throughout the State is shown. Some cities have an exceptionally favorable rate. Others are highly unfavorable.

Now let us consider the significance of these figures and observations.

DISCUSSION

The decrease in the total death rate is due almost entirely to the decrease in the rate for puerperal albuminuria. This is a reflection of the work of the Massachusetts Medical Society, in prenatal care. The results are so favorable that it must be strongly urged to continue the good work. In general the puerperal albuminuria situation is better than formerly for this year's rate is about twenty per 100 000 of the total population.

The same cannot be said of puerperal septicemia which has had its ups and downs. This is a difficult problem. However, the advice of this Section of the Massachusetts Medical Society to practice antiseptics diligently, is well grounded by the figures. A careful physical examination is also helpful.

Due to the decrease in puerperal albuminuria and puerperal septicemia other causes of death are becoming relatively more important. These are as follows: (1) embolism, No 148, (2) hemorrhages, No 144, (3) accidents, No 149. If the deaths ascribed to embolism were correctly diagnosed, then we face another difficult situation. For we cannot at the moment do much to prevent embolism.

The number of deaths from the International List cause No 144 (puerperal hemorrhages), is great enough to warrant an attack by the best skill and judgment of all practicing in this field.

The item No 149, accidents, is somewhat vague. It is, however, remarkable that one-third of all accidents, which is five per cent of all maternal deaths, can be attributed to those conditions where cesarean section was employed as a surgical measure. This indicates the gravity of the decision to use the cesarean operation.

Now a few words regarding the distribution over the State are in order. Some cities have a very favorable death rate. Others are very differently situated. As the standard of medical skill varies but little from place to place in Massachusetts, we are forced to seek other causes to explain this erratic distribution. It appears from a consideration of the characteristics of the various regions that social and economic factors are playing the dominant part.

In conclusion we may remark that the general trend of the death rate is favorable. These results justify the efforts which this Section has already made. They provide the basis for a genuine optimism. On the other hand the analysis of the causes indicates the points where fur-

ther efforts would bring great results. It therefore behooves the Section to continue its vigorous efforts, for the prize is great.

DISCUSSION

CHAIRMAN ALMY The discussion will be opened by Dr Kellogg.

DR FOSTER S KELLOGG, Boston Mass. Dr Mongan's paper marks a summary of the educational work of this Section to date. The results he reports are a tribute to the efforts of the Section, to the men who have worked hardest for it, and to him, in particular, because I think he conceived the idea. The figures that he presents appear to show the value of persistent work throughout the year. This has been the underlying idea of the Section from the beginning. And since it was his idea primarily and he has always given unselfishly and completely of his time and himself to it, I think his position as an educator in obstetrics in this State is equal to that of any of our men of professorial rank in the schools.

I will discuss one or two points in the paper very briefly. In the first place, the one apparently outstanding improvement that has been made is in the group of hypertension albuminuria cases. This is due, as Dr Mongan has said, to greater attention to prenatal care, but also to the advice which the Section has carried through the State, that patients with pre-eclampsia and albuminuria and hypertension should be hospitalized early and if they fail to improve on medical treatment in hospital, delivered by the gentlest possible means.

In the last fifteen or twenty years at the Boston Lying In Hospital, since accouchement forcé was abandoned, we have saved no patients by altering our treatment of eclampsia but have saved a good many by earlier treatment and delivery in pre-eclampsia. So this seems, in the light of the present lack of knowledge, a good system to pursue.

In the second place, it is discouraging to note our failure to improve results in the bleeding cases in the State. Those of us who have done the educational part of the program are perhaps somewhat to blame for this. We have gone about preaching that every patient who bleeds antepartum must be considered a placenta praevia unless proved otherwise. Some of us also have agitated quite strongly the delivery of most placenta praevias by Caesarean section. It is possible that some patients who have had antepartum bleeding have been subjected to Caesarean section without the diagnosis of placenta praevia having been established.

This brings us directly to my third consideration. Dr Mongan reports a high mortality in Caesarean section cases throughout the State. It seems probable that, as for many years in the past, too many Caesarean sections are done and they are not done under careful enough indications. Though individuals seem capable of doing long series of abdominal deliveries with no mortality at all these happy results seem never to get into state-wide statistics, and the moral that we must all draw from this is that in each individual instance, we should think twice before we subject a patient to Caesarean section.

Last, the mortality from sepsis. This rate will diminish if we adhere to the rule that, whenever possible, a patient shall be allowed to deliver herself normally, without instrumentation, and that especially we will never operate through the undilated, partially dilated, or so-called dilatable cervix. In hospital we will avoid the periodic exogenous throat infection epidemics if we insist on all contacts with the patient's perineum being masked throughout labor and throughout puerperium.

I thank you for your kind attention.

CHAIRMAN ALMY Dr DeNormandie will continue the discussion.

DR. ROBERT L. DENORMANDIE When Dr Mongan handed me his paper to read he said he hoped that if I differed from him I would frankly say so, for by that means he hoped discussion would be stimulated. I am going to take him literally and differ from him, thereby hoping that others will carry on.

At the present time most statistical studies on maternal mortality are based on rates determined in relation to 1,000 live births. Dr Mongan has, however, used rates calculated upon the basis of 100,000 of the population. The rates as he has given them are not, therefore, comparable to many reports that have already been published. To be sure, such rates are published from time to time, but usually only when the more accurate method, that in relation to the number of live births, is not available. In Massachusetts this latter method is available, and I regret that Dr Mongan did not use it. The Fifteen States Study, the New York and the Philadelphia Studies are all based on the rates per 1,000 births.

In table 2 Dr Mongan has given us the results of adding together rubrics 140—Septic Abortion, and 145—Puerperal Septicemia, of the International Classification. This seems wholly justifiable, but in table 3 he shows the rate for puerperal albuminuria to be 3 per cent in 1923, dropping to 67 per cent in 1934, that is, 130 cases in 1923 and twenty-nine in 1934. The reason for this decided improvement he does not state, but it was due chiefly to the changes in the 1929 revision of the Manual of the International List of Causes of Death. In this revision, rubric 145 became "Puerperal Albuminuria and Eclampsia," and 147 became "Other Toxemias of Pregnancy." To show the correct picture, these two rubrics should be added and the percentages calculated from these figures. On this basis the maternal death rate in eclampsia and toxemia becomes in

	1931	227			
	1932	189			
	1933	172			
	1934	186			
146 Puerperal albuminuria and eclampsia	52	35	41	29	
147 Other toxemias of pregnancy	41	35	26	30	
	93	70	67	59	

The last three years are better than 1931, but 18 per cent of the total deaths cannot be considered "a small contributing factor" of maternal mortality. The situation undoubtedly has improved, but there is still great room for effort and improvement.

Dr Mongan states that rubric 149—Other Accidents of Childbirth—is somewhat vague. But is it? It is divided into two parts.

- (a) Caesarean operation Porro's operation
- (b) Others under this title

Caesarean section is not vague. The second subdivision takes in the various obstetric operations—breech, rupture or inversion of the uterus, rupture of the bladder, malpresentation. It seems perfectly clear what the intent of this division is—death from difficult delivery.

I do not believe the whole story of Caesareans is explained by saying that 5 per cent of all the maternal deaths can be attributed to Caesarean section. I am confident that there were more. If each death were studied, Caesareans would be found under at least three other rubrics—namely, 144—Hemorrhage, 145—Sepsis, and 146—Puerperal Eclampsia. I do

not believe "Caesarean operation *per se* should ever be accepted as a cause of death. Caesarean section does not kill. It is the condition for which it is done hemorrhage or eclampsia, or the complication of sepsis which follows, which kills and therefore the death should be put in the proper rubric and not under Caesarean operation.

I take it that most of the deaths in this section were due to poor operative obstetrics either in the choice of operation or lack of skill in performing it. It would have been most interesting if Dr Morgan could have told us how many times operative procedures preceded death in this group.

Dr Morgan I think, questions the correct diagnosis of so many cases of embolism. I too question the diagnosis. Some undoubtedly were rightly ascribed to embolism but embolism sounds much better than rupture of the uterus following a hard forceps or version. The diagnosis of embolism is accepted by the registrar usually without question.

I agree that there has been a slight improvement in the general trend of the death rate but I can not subscribe to the statement that it provides a basis for genuine optimism. The effort of this Section must be to reduce the number of these deaths. It is not alone a medical problem. The social and economic condition of the patients plays a part. The Section can do no greater good than to popularize throughout the State the meaning of good adequate conservative maternity care. Then each one of us must live up to this standard.

In order to accomplish this purpose I believe that in each of the District Societies a committee on maternal welfare should be appointed. It would be incumbent upon these committees to hold meetings for the purpose of showing what adequate maternity care is. These committees should follow up carefully each maternal death in their district. The deaths should be studied on the same schedules so that they would be comparable, and each year a short report should be made in regard to progress. The formation of such committees would be in line with what the American Committee on Maternal Welfare is doing throughout the country and what it wishes. By this means the entire State would be covered, no undue amount of work would be put on any one committee and the whole could be carefully compiled each year into a most valuable report. By this means the Section could have a real power to the State for demanding good sane obstetrics.

CHAIRMAN ALMY. The paper is now open for discussion from the Section.

Dr. SAMUEL GWYNNE, Worcester, Mass. I would like to ask Dr Morgan if he has any figures as to whether those Caesareans were done by general surgeons or whether they were done by obstetricians.

CHAIRMAN ALMY. Dr Morgan do you care to close the discussion?

Dr. MORGAN. In answer to Dr Gwynne there is no way of knowing when a surgeon is an obstetrician and when an obstetrician is a surgeon. Dr DeNormandie says it is a live issue. He and I apparently agree. I think this chart was presented by the State Department of Public Health. Dr DeNormandie?

Dr. DeNORMANDIE. Yes.

Dr. MORGAN. And the State Board of Health is not the official source from which maternal death rates or any death rate is collected in Massachusetts. Keep that in mind. That is the first thing I do not criticize Caesarean operations. I said that a certain number of deaths occurred where the ob-

stetrical procedure of a Caesarean operation was employed. Dr DeNormandie says that if we look farther we might find more deaths in which the surgical operation of Caesarean section was employed. Yes. I didn't report them all. Some are under hemorrhages which happened after the Caesarean operation was performed. Since 1929 Caesarean operations have a separate classification. I think that is a misleading classification. I would rather have the reasons why the obstetrician felt it necessary to perform Caesarean operations.

The classification of "the toxemias of pregnancy" has been changed. Let me tell you the history. The international classification of diseases was the outcome of an agitation brought about by Bertillon the French scientist who invented finger printing. It was he who called together representatives of all the civilized countries of the world to determine and agree upon a system of classifying deaths. This list has been revised every ten years. The last revision was in 1929 partly through the agitation of this Section which sent a message through the American Medical Association to the Chief of the Census Bureau in Washington when this Section met in Swampscott in 1924 requesting this change in classification. Were all the toxemias of pregnancy under the old classification put under albuminuria of pregnancy? No they were not. They are not today. There are now two classifications. One—146—"Puerperal Albuminuria and Eclampsia" and 147 "Other Toxemias of Pregnancy."

We do think that there has been a decided change in the albuminuria of pregnancy. We also think that the reporting of the other toxemias of pregnancy should be more specific. I should hope that no one listening to my paper could think for a moment that we were going to give up our work of striving to eliminate albuminuric pregnancy. If I created that impression it is one that I did not wish to express. Every month there is submitted to me from the Department of the Secretary of the State a list of all the diagnoses of deaths occurring in the puerperal state in Massachusetts. I suppose in the last fifteen or eighteen years I have studied and reviewed over 5,000 death certificates some of them written by men here. On the whole these certificates are a credit to your professional ability. There are very few of these certificates that in any way indicate that the reporting physician was trying to camouflage or evade any condition which it was his duty to report. There are some however which are open to question.

When you write a death certificate in a puerperal case, be specific, be short. Know what you are going to say and say it honestly. If the patient did die of puerperal septicemia say so. There isn't any man practicing obstetrics over a period of years but must have had that sad duty to perform. If it was eclampsia, say so. No matter what the actual condition was say it succinctly and precisely. Then these lists of causes of deaths will amount to something.

Remember toxemias were not classed in the old days under albuminuria. Puerperal septicemia the British call it a riddle and I call it a riddle too. It sometimes varies with the seasons. When there is a large amount of puerperal septicemia prevalent it occurs here and all over the world. It seems sometimes as if we had reached a point where we can make no impression on it. We are not the only country that has septicemia to deal with nor are we the only country that is studying the problem. In studying the subject let us use statistics gathered by Massachusetts physicians and not those statistics collected in a manner we do not know about. I thank you.

CHAIRMAN ALMY. The paper on "Puerperal Neu-rectomy" will be read by Dr Frank A. Pemberton Professor of Gynecology at Harvard College.

RESECTION OF THE PRESACRAL NERVE IN GYNAECOLOGY*

BY FRANK A PEMBERTON, M D †

THE presacral nerve, or superior hypogastric plexus, is a network of nerve fibres, or rarely a single nerve, extending downward from just above the bifurcation of the aorta for a distance of about five cm. It lies in the areolar tissue between the peritoneum in front and the aorta, left common iliac vein, and sacrum behind. It is part of the autonomic nervous system and is composed mostly of fibres from the sympathetic division of that system.

The fibres come from the inferior mesenteric plexus and adjacent lumbar ganglia of the sympathetic system which, as they enter the pelvis, spread out forming a triangle at the lower corners of which are the inferior hypogastric plexuses. From these, fibres run down to the pelvic ganglia on each side of the pelvis of which they are the sympathetic roots. They are joined here by fibres from the sacral part of the spinal cord which constitute the parasympathetic roots of the pelvic ganglia. From these ganglia nerves run to the various pelvic organs. This description was obtained from Livingston¹ and Davis².

The presacral nerve itself is not often a single nerve. Davis reports that in eighty-five per cent of his cases it was a plexus of fibres and in fifteen per cent one nerve. All of our cases have shown a poorly defined bundle of many small fibres with one or more easily seen nerves among them in a few cases. We have demonstrated nerve fibers in the tissue removed from all our cases by means of the microscope.

According to Livingston who sums up the opinion of many authorities, the autonomic nervous system sends out impulses to the visceral organs. It is thought from its anatomical arrangement and experimental data that the sympathetic division is used for a wide diffusion of impulses while the parasympathetic division carries impulses to single organs to produce specific and local effects. Further there is a theory that these two divisions work antagonistically to each other and maintain a balance when they function normally. There is experimental evidence both for and against it, so the problem is not solved but it makes a good working plan for clinical application at present. It is believed that the sympathetic division maintains tonicity of the blood vessels because it causes constriction of them when it is stimulated while the parasympathetic has the opposite effect. The sympathetic nerves produce their effects by elaborating a substance called sympathin at the nerve endings, a substance which seems to be identical with adren-

alin. The other division similarly elaborates a substance called acetyl-choline.

The autonomic nervous system does not complete all its reflexes through the spinal cord, for centers in the brain which control it have been found but their limits have not been defined.

Finally there is an afferent system of visceral nerves which carries impulses from the viscera to the central nervous system. These impulses are largely subconscious but when the integrity of an organ is threatened by disease these impulses reach consciousness as pain of varying intensity.

We are concerned primarily with the presacral nerve and its function. It is said by both Livingston and Davis that its sympathetic fibres cause relaxation of the intestinal musculature and an increase in the tone of the sphincter muscle because cutting it in chronic dilatation of the colon, Hirschsprung's disease, is followed by contraction of the intestine. The theory is that the operation gives the parasympathetic nervous system a better chance to excite contractions of the muscle. It is supposed that there may be a similar control of the uterine and bladder musculature.

The presacral nerve probably controls the tone of the blood vessels in the genital organs. It is not uncommon after presacral neurectomy for the patient to flow from the uterus for a few days even though menstruation has ended just before operation. Cutting the sympathetic supply may allow the parasympathetic to cause dilatation of the vessels which could account for the bleeding. Many cases of essential dysmenorrhea have sclerocystic disease of the ovaries which theoretically may be due to some effect on the blood supply from an imbalance in the autonomic nervous system.

The presacral nerve, according to Livingston, probably contains fibres of the afferent visceral nervous system as well as its sympathetic part, because cutting it relieves pain in dysmenorrhea, diseases of the bladder and cancer of the pelvic organs. It usually relieves the pain immediately but since it does not do so always Davis suggests that the effect may be obtained by stopping an imbalance in the vasomotor apparatus. This is a subject of discussion with no satisfactory explanation. If the autonomic nerve control of the uterus is analogous to that of the large intestine one would suppose that removing the sympathetic division would allow the parasympathetic to excite stronger contractions of the uterine muscle and increase dysmenorrhea rather than relieve it. Either dysmenorrhea is not due to muscle contractions, the pain is caused by blood vessel spasm from the

*Read at the Annual Meeting of the Massachusetts Medical Society, Section of Obstetrics and Gynecology, June 3, 1935.

†Pemberton, Frank A.—Clinical Professor of Gynecology, Harvard University Medical School. For record and address of author see 'This Week's Issue' page 730.

action of the sympathetic system or the pain has nothing to do with the autonomic nervous system and relief is obtained by cutting the afferent visceral nerve fibres in the presacral nerve which carry pain sensations.

Clinical reports offer no good explanation of why presacral resection should be as effective as it is. It is used as a gynecological procedure to relieve pain in dysmenorrhea, malignant diseases in the pelvis, and idiopathic pain. Some writers mention beneficial effects in priapismus vulvae.

In essential dysmenorrhea it should be used as a rule, only after all other methods of treatment have failed. One should remember that hygiene, regulation of habits of body and mind and medicine should be given a thorough try first. If these fail then operation may be considered. Whether to do a dilatation of the cervix alone and reserve presacral neurectomy for cases in which dilatation fails or to do both right off is a matter of individual selection depending on the severity of the symptoms and the patient's mental attitude. We believe that if the patient has reached full growth that is the age of twenty one, it is useless to temporize and both procedures had better be carried out. Further we believe that if the uterus is retroverted or anteverted and retrocessed that a suspension of the uterus aids in relief so we do that also and as a result have only one case to report who has had simply a dilatation of the cervix and presacral neurectomy.

In dysmenorrhea due to pathological conditions in the pelvis this operation is combined with the removal of diseased organs or correction of versions to make success more certain.

We have debated the use of this procedure in conservative operations for diffuse endometriosis for fear that we might implant the disease retroperitoneally but are inclined to the opinion that if the neurectomy is done as a first step in the operation as a whole the danger is slight enough to be disregarded.

We have discarded it for the time being in patients suffering from pain due to advanced cancer of the cervix because the injection of alcohol into the spinal canal has been so satisfactory. Resecting the nerve means an abdominal operation with its attendant hospital stay and period of convalescence for a patient who is in poor condition with not very long to live anyway.

There seem to be no permanent deleterious effects caused by the operation. There are reports that postoperative catheterization is necessary more often and that a residual urine occurs but it is for two or three days only. It has no effect on childbirth. Fontaine and Herrmann¹, Wetherell², De Courcy³ and others report normal pregnancies and labors following the operation. Wetherell⁴ reports the relief of obsti-

nate constipation in one case as well as the beneficial effect on her dysmenorrhea.

Section of the nerve does not alter the normal menstrual cycle except for the bleeding which follows the operation in some cases. Menstruation which has been scanty or profuse usually returns to normal.

De Courcy³ reports twenty-one operations done for dysmenorrhea with excellent results. Greenhill⁵ has done it in both essential and other dysmenorrheas and recommends it. Counseller and Craig⁷ have had a similar experience in fourteen cases. There are many satisfactory reports from Europe where the operation was first performed in France thirty years ago but discarded until about ten years ago.

There are very few reports of its use to relieve pain in advanced cancer of the cervix. Behney⁸ cites twenty-two cases. Sixteen were relieved of the pain but seven lived less than four weeks after the operation.

The technique of the operation is not so simple as the various reports say in our opinion. The peritoneum over the bifurcation of the aorta is opened by a longitudinal incision which is enlarged to about ten cm in order to obtain sufficient exposure over the lower end of the aorta and well down on the sacrum. One sees areolar tissue with nothing distinctive about it until a close inspection shows small nerve fibres running through it and sometimes a well defined nerve or two. We lift the peritoneum and clear its under surface carefully out to the ureter on the right and the inferior mesenteric artery on the left, which may have to be pushed aside in some cases in order to reach all the fibres. Then a triangular space from just above the bifurcation of the aorta downward for about five cm is cleared of all areolar tissue and nerve fibres. At the apex we have often cut small vessels which needed ligation and similar ones at the lower corners of the triangle. The middle sacral artery can be avoided usually but we feel sure that it has been cut twice in our series without damage. One must be careful to avoid injuring the right ureter, inferior mesenteric artery and left common iliac vein which lies on the left in the posterior wall of the triangle. The incision in the peritoneum is closed with fine catgut.

We have a series of forty-one cases who have had a presacral neurectomy, twenty-five done by various members of the staff of the Free Hospital for Women and sixteen by the author in his private practice.

Fifteen patients had no other pathology than some form of underdevelopment of the pelvic organs and had never been pregnant. That is they had essential dysmenorrhea. Their ages varied from sixteen to thirty-seven with an average of twenty-six. They were all twenty-one or over except one girl of sixteen who was operated on

primarily for appendicitis, and presacral neurectomy was done because she had severe dysmenorrhea. We think it is evident from these age statistics that we have been very conservative in the application of this new operation. They are patients who had had medical methods tried first in most cases without relief. The operation in fourteen consisted of a dilatation of the cervix, a suspension of the uterus by Olshausen's method, and an incidental appendectomy as well as the neurectomy. We do a suspension of the uterus because experience has shown that it helps in the cure of dysmenorrhea, and feel that everything should be done. Therefore we have only one case which had a dilatation and presacral neurectomy alone done for essential dysmenorrhea.

The time since operation varies from two to thirty-six months with an average of fifteen.

Twelve (80 per cent) of these fifteen patients were relieved, one (7 per cent) had partial relief, and two (13 per cent) had no relief. The one with partial relief has pain with every third period on the average so she is much better. We cannot explain why this should be. The two with no relief are recent cases each having had only two periods since operation which were just as painful as before. There is nothing distinctive to show why they were not relieved and it seems as if the whole nerve should not have been removed.

Dilatation of the cervix alone gives relief in about fifty per cent of cases while dilatation and suspension relieves about sixty-five per cent, so the addition of the neurectomy is of distinct benefit. Therefore it may be sensible to change our rule of waiting until the patient has reached her full growth and do it on those who have had thorough medical treatment followed by a simple dilatation of the cervix without relief.

Presacral neurectomy may be used as an adjunct in treating dysmenorrhea due to pathological changes in the pelvis. We have so used it on eighteen patients who had conservative operations of various kinds. The main diseases were as follows: pelvic inflammation in seven, prolapse in seven, fibromyoma of the uterus in two, and endometriosis in two. They had various types of conservative operations all of which included a suspension of the uterus and a presacral neurectomy. We have lost track of one. Eleven were relieved of the dysmenorrhea, four had partial relief and two no relief. One is pregnant and one has had a normal labor since operation. Some of them have minor pelvic pain of an aching character which is not bad. It is our impression from studying these cases that cramp-like pain is relieved by the neurectomy because of the common statement by the patient that her cramps are gone but she has some aching at times, apparently depending on how bad the original pathological

condition was and the condition in which the pelvis was left. The type of operation done on these patients differed so much that no exact conclusions can be drawn. Neurectomy adds little to the risk and should be done in an attempt to use every effort to obtain relief.

Two patients had hysterectomies and bilateral salpingo-oophorectomies for pelvic adhesions due to a previous inflammation as well as a neurectomy and are entirely relieved. How much the neurectomy had to do with the cure is uncertain but it may be of value as shown by the next case.

This woman of thirty-four had a conservative operation for pelvic inflammation in 1929. She came to the author in 1931 complaining chiefly of a dull ache with sharp pain at times in the left lower quadrant. He found the pelvis full of adhesions, and the uterus, tubes and ovaries so damaged that it was necessary to remove them. She made a normal convalescence but continued to have the same pain. The urinary and gastrointestinal tracts were negative to x-ray examination. Medical and orthopedic consultations were negative. In 1933 the patient demanded that something be done and following a presacral neurectomy she has been well.

A spinster of sixty-eight had had a hysterectomy and bilateral salpingo-oophorectomy seventeen years before. She complained of sharp pain in the lower abdomen of three months' duration and frequent burning micturition of ten days' duration. On November 9, 1932, a pyelogram was done with negative findings. A gastrointestinal x-ray was negative. She was treated by means of bladder dilatation and irrigation without improvement. On March 31, 1933, operation by the author revealed a loop of sigmoid adherent to the bladder over an area of about four square inches. This was separated and the presacral nerve removed. The interesting point in this case is that the patient said three days after operation that the sharp pain had gone and all she noticed was some irritation which seemed to be in the urethra. This irritation subsided and she felt well in a month. There is no proof that the neurectomy helped in the cure but it seems very possible.

Therefore in cases similar to the last four we are inclined toward doing a presacral neurectomy with the hope that it may aid in the cure although it will be a difficult proposition to prove.

We have used the operation in four cases of cancer of the cervix to relieve pain without success. They had widespread growths in the broad ligaments and retroperitoneal areas. In this disease the operation is done on patients who have not much longer to live anyway. More important however is the fact that the injection of alcohol into the spinal canal to destroy the sensory roots has been successful at the

Free Hospital for Women It is simple to do, effective, and so far has not been followed by complications. This will be made the subject of a report by Youngs at a later date.

SUMMARY

Presacral neurectomy relieves dysmenorrhea of the essential type and may help in that due to pathological conditions.

It is apparently of value in stopping idiopathic pelvic pain and pain due to malignant growths.

It has no deleterious effect on pregnancy and labor and may restore irregularities of menstruation to normal. The mechanism of its action is not definitely known.

DISCUSSION

CHAIRMAN ALMY Dr James C White will open this discussion.

DR. JAMES C. WHITE Dr Pemberton has given you an excellent exposition on the value of resection of the superior hypogastric plexus in gynecology. His is the largest series on record in this country and it seems almost presumptuous to add our small number of seven cases from the Massachusetts General Hospital. These have been operated on by Dr J V Meigs and me. The only thing that is significant about our series among the large number of favorable case reports which have appeared in the literature is that in six of our cases we have carried out no other procedure besides presacral neurectomy and routine appendectomy. For purposes of control retroverted uterus were left retroverted, and the pain was wholly relieved in all but one instance (and she is none the less definitely better). These cases have been followed from six months to four and one-half years. Now that the effectiveness of cutting the viscerosensory nerves from the uterus has been so well established, we agree that routine suspensions and any necessary procedure on the tubes or ovaries should be carried out at the same time. In corroboration of Dr Pemberton's statistics none of these patients have complained of any postoperative difficulty with urination or any other disturbance. In this connection the recent anatomical observation of Stanford and Telford should be emphasized—that the pelvic parasympathetic supply which stimulates the lower colon to normal defecation travels upwards in the hypogastric nerves. If the presacral nerve dissection is carried too far down into the pelvis these fibres may be cut as they branch off to join the superior hemorrhoidal artery. On the other hand the operator who fails to dissect downwards far enough will fail to destroy

the ramus from the fourth lumbar ganglion which runs under the common iliac vessels. I believe that this is a cause of occasional failure, and that the surgeon should not be satisfied until he has thoroughly dissected the triangle below the aortic bifurcation down to the origin of the internal iliac vessels.

I believe that the relief of pain which follows this operation is directly due to the cutting of visceral pain pathways. From a strictly anatomical view point the presacral nerve like the splanchnics and the cardiac nerves contains a majority of small unmyelinated sympathetic motor fibres. It also carries a certain number of large myelinated neurones which Heinecker has shown are identical histologically and in their electrical conduction properties with ordinary sensory nerves to the skin like the saphenous. Furthermore these fibres come from the posterior spinal sensory roots and are therefore identical with ordinary sensory nerves to other parts of the body.

CHAIRMAN ALMY Dr Louis E Phaneuf will continue the discussion.

DR. LOUIS E PHANEUF Boston, Mass. *Mr Chair* man and Members of this Section—

Dr Pemberton has brought to our attention an important method in the treatment of intractable primary spasmodic dysmenorrhea.

Three groups of nerves are concerned in the innervation of the female genital apparatus—(1) the pelvic sympathetic superior hypogastric plexus of Hovellacque presacral nerve of Latarget (2) the utero-ovarian nerves and (3) the pudendal nerve from which the perineal nerve arises. The first two innervate the internal genital apparatus and the vagina, while the third supplies the external genital organs and the perineum.

Resection of the presacral nerve for dysmenorrhea was popularized by Gaston Cotte of Lyon, France in 1924. Cotte has written an excellent book entitled *Chirurgie du sympathique pelvien* Masson & Co, Paris 1933. In this book the indications and technique are well described. Since 1924 several papers and case reports have appeared in the literature. Among the American contributions may be mentioned those of Adson and Manson, Elant, Fontaine and Herrmann, Greenhill, and Wetherell.

A symposium on 'pain in gynecology' was presented before the second Congress of the French Gynecological Society in 1933. Cotte presented one of the reports at this Congress. In his paper he reported more than thirty pregnancies following presacral neurectomy in his series. In all of these cases the deliveries were normal and without complications. He stated that he had not encountered any trophic disturbances or atrophy of the vulva and vagina following this intervention.

From the standpoint of technique he advises against trying to isolate the sympathetic fibers but advocates the removal of about 3 cm of the cellulosic membrane which is found under the peritoneum and which contains the fibers. The tissue removed should be examined histologically to demonstrate these nerve structures.

At the same Congress L. Aubert of Geneva, in discussing Cotte's report gave the details of his sixty presacral resections. In this group he reported but two failures. Pregnancy had ensued in a few of his patients who had had normal labors.

I am in complete agreement with Dr Pemberton that this operation valuable as it may be should be used cautiously since dysmenorrhea, in many instances, may be relieved by medical endocrine and other surgical means. It should be reserved for

those patients who have not been helped by the ordinary methods of treatment. Since, in the past, some of these women have been treated by hysterectomy, radiation and oplates, it seems logical that in the future these procedures should be supplanted by a resection of the superior hypogastric plexus, bearing in mind, however, that the intervention carries the risk of a laparotomy

Personally I have done but three presacral resections. The operation is not difficult if one has the anatomy of the parts clearly in mind. For my part, I examined the superior hypogastric plexus in several anatomical subjects to familiarize myself with the landmarks before performing my first operation. All three of my patients were relieved of pain in their subsequent menstruations. The first patient so operated realized that she was menstruating when blood appeared on her clothing the period being absolutely painless, although before the intervention she was so crippled from dysmenorrhea that she had to remain in bed and resort to oplates. I have had no experience with presacral neurectomy for carcinoma of the cervix or for pruritus vulvae, although there are reports in the literature to the effect that relief may be obtained in these two lesions by resecting the presacral nerve.

Dr Pemberton has shown us a useful procedure, which, when employed in properly selected cases, is attended with uniformly good results.

CHAIRMAN ARMY. The paper is open for general discussion.

DR JOHN FALLON, Worcester. After you have heard the story of so rich an experience as this, I would not dare to get up and talk about my own, which is limited to seven cases, if I disagreed with Dr Pemberton. But I don't. I agree with every thing he has said, and would only add two minor ideas.

First. The operation promises well, is still, at least on this side of the water, a shade experimental. Not difficult, it requires a little special knowledge and technique (helped, by the way, by Cushing clips). Therefore it is not something to recommend for every dysmenorrheic maiden who happens to see us. Dr Pemberton said as much. I would add the corollary. When the abdomen of a dysmenorrheic is already open, for whatever reason, it seems not only justifiable but desirable to add this step to whatever is being done, if it is technically feasible.

Secondly. The patient with enough recurrent pelvic carcinoma to give intractable pain and, unfortunately, enough strength to last some time, seems to be the ideal subject for study. Three of my cases were in this group, and the three did well—probably from luck possibly because a wider sympathectomy was done. The resection included the presacral plexus, lower two lumbar ganglia on each side, inferior mesenteric and iliac nerves. Surgically more radical, this seems less radical physiologically than intra arachnoid alcohol.

CHAIRMAN ARMY. Unless there is some more business to come before this Section, the meeting stands adjourned.

OBSERVATIONS ON THE SYMPTOMATOLOGY OF CHOLELITHIASIS*

With Special Reference To Vomiting

BY ROBERT ZOLLINGER, M.D.,† AND EDMUND YOUNG, M.D.†

WE became interested in the symptomatology of cholelithiasis after studying several patients whose pain varied from the typical syndrome of biliary colic. Since the pain is often the result of overdistention of the gallbladder or major bile ducts by a calculus, we attempted to simulate this by mechanical means in conscious patients. By such a method we hoped to study the symptoms produced by distention of the gallbladder as compared with distention of the major extrahepatic ducts. In this report a clinical study, based on our experimental findings, has been undertaken in an effort to evaluate the symptoms of cholelithiasis in relation to the location of the offending calculus.

Our observations consisted of the mechanical distention of the gallbladder or common duct in six patients¹. Under a short gas-oxygen anesthesia or local infiltration of novocain the stones were removed from the gallbladder or common duct and a sterile balloon was inserted which could be distended and the pressure recorded. When the patient had recovered sufficiently from the anesthesia to answer all questions intelligently the gallbladder or common duct was

distended. Distention of the gallbladder produced a feeling of indigestion or deep epigastric discomfort without the usual referred pain to the back or discomfort in the right hypochondrium. Nausea and vomiting did not occur regardless of the degree of distention. Distention of the common duct produced a more severe epigastric distress but again pain was not referred to the back. Inspiratory distress was characteristic of distention of either viscus. The chief difference between distention of the gallbladder and of the common duct was the occurrence of nausea and vomiting with the latter.

The significance of these observations was then determined from a study of the clinical histories of three hundred cases previously operated upon in the Peter Bent Brigham Hospital for cholelithiasis. Particular reference was made to the location of their initial pain and the occurrence of involuntary vomiting. These cases were divided into three groups of one hundred cases each. The first group included only patients with cholecystitis and cholelithiasis who had never been jaundiced and in whom no evidence of cystic or common duct calculus could be found at operation. As far as could be determined in this control group the ducts had not been distended by a calculus, and the symp-

toms resulted from stones within the gallbladder. All of the second group had acute cholecystitis. The cystic duct was occluded by a stone in forty of these patients, and probably in many more not mentioned in the pathologist's or surgeon's note. The third group of one hundred cases had calculi removed from the common duct at operation.

One hundred cases

One hundred cases

some of the more common symptoms in cholelithiasis as it occurred in the three hundred cases. Involuntary vomiting interested us especially since it occurred experimentally only when the ducts were dilated. We believed it might prove of value in the differential diagnosis between stones in the gallbladder as compared with the symptoms of stones in the cystic or common duct. By involuntary vomiting we mean spontaneous vomiting and not induced vomiting following nausea. Unless there was a specific statement to the contrary, we considered the vomiting described in the clinical history to be spontaneous. It occurred in twenty nine of the one hundred cases of chronic cholecystitis with out evidence of calculi in the cystic or common duct. Vomiting was found in eighty five of the one hundred cases of acute cholecystitis. Obstruction in the cystic duct no doubt accounts for the high incidence in this group. As we expected, the highest incidence of vomiting (eighty nine per cent) occurred in the one hundred cases of proved common duct stone. We believe that the clinical and experimental observations coincided rather closely, in that distention of the ducts does produce vomiting in contrast to its absence in distention of the gallbladder. Obviously it cannot be determined how many cases of vomiting in the group of chronic cholecystitis may have been due to a stone temporarily blocking the cystic duct. These findings suggest that pronounced involuntary vomiting in

cases of cholelithiasis often indicates that a stone is impacted in the ampulla of the gallbladder or located in the major extrahepatic ducts. The surgical significance of this observation is apparent and we believe that involuntary vomiting should be added to the commonly accepted list of indications for exploration of the common duct.

Attacks of colicky pain occurred in sixty per cent of the cases of chronic cholecystitis and cholelithiasis. The percentage was increased to eighty in acute cholecystitis and ninety in cases of common duct stone. It must be remembered that common duct stones can occur without pain. There is no mention made in these histories of the association of inspiratory distress with colic, but in a study of our recent cases we find it to be associated with gallstone colic in over twenty five per cent. We are convinced of its diagnostic significance in cases of biliary colic.

Right upper quadrant pain occurred in almost two-thirds of the three hundred cases. Left upper quadrant pain or bizarre and atypical localization in about five per cent. On the other hand, epigastric pain appeared as the initial symptom in more than one third of the cases. Since the epigastric pain was the only type produced by our mechanical distention of the gallbladder or common duct, we believe that this symptom indicates a similar process resulting from a calculus blocking or trying to pass through one of the major ducts. Closer questioning of the patients would undoubtedly elicit the fact that often the onset of pain was localized in the epigastrium. This, we believe to be a visceral type of pain. The high incidence of pain in the right upper quadrant may be accounted for by an associated inflammation of the gallbladder stimulating the adjacent cerebral spinal nerves. We cannot offer a satisfactory explanation for the referred pain to the back so often found in biliary colic.

Jaundice occurred in eleven of the one hundred cases of acute cholecystitis and in ninety of the one hundred cases of common duct stone. We have found involuntary vomiting to occur as often as jaundice in the presence of a common duct stone, and we have occasionally accepted it as the chief diagnostic symptom. A recent or past history of jaundice is an indication for exploration of the common duct. However it must be remembered that ten per cent of the common duct stones occurred in the absence of jaundice.

Although both chills and fever are usually considered to be inseparably associated with jaundice in the presence of a stone in the common duct, we found to our surprise that they were mentioned in only fifteen of our one hundred proved cases. Close questioning of our recent patients showed that they certainly are not present in over one-third of the cases.

The average age of the one hundred cases of

those patients who have not been helped by the ordinary methods of treatment. Since, in the past, some of these women have been treated by hysterectomy, radiation and opiates, it seems logical that in the future these procedures should be supplanted by a resection of the superior hypogastric plexus, bearing in mind, however, that the intervention carries the risk of a laparotomy.

Personally I have done but three presacral resections. The operation is not difficult if one has the anatomy of the parts clearly in mind. For my part, I examined the superior hypogastric plexus in several anatomical subjects to familiarize myself with the landmarks before performing my first operation. All three of my patients were relieved of pain in their subsequent menstruations. The first patient so operated realized that she was menstruating when blood appeared on her clothing, the period being absolutely painless, although before the intervention she was so crippled from dysmenorrhea that she had to remain in bed and resort to opiates. I have had no experience with presacral neurectomy for carcinoma of the cervix or for pruritus vulvae, although there are reports in the literature to the effect that relief may be obtained in these two lesions by resecting the presacral nerve.

Dr Pemberton has shown us a useful procedure, which when employed in properly selected cases, is attended with uniformly good results.

CHAIRMAN ALMY: The paper is open for general discussion.

DR JOHN FALLON, Worcester: After you have heard the story of so rich an experience as this, I would not dare to get up and talk about my own which is limited to seven cases, if I disagreed with Dr Pemberton. But I don't. I agree with every thing he has said, and would only add two minor ideas.

First: The operation promises well, is still, at least on this side of the water, a shade experimental. Not difficult, it requires a little special knowledge and technique (helped, by the way, by Cushing clips). Therefore it is not something to recommend for every dysmenorrheic maiden who happens to see us. Dr Pemberton said as much. I would add the corollary: When the abdomen of a dysmenorrheic is already open, for whatever reason, it seems not only justifiable but desirable to add this step to whatever is being done, if it is technically feasible.

Secondly: The patient with enough recurrent pelvic carcinoma to give intractable pain and, unfortunately, enough strength to last some time, seems to be the ideal subject for study. Three of my cases were in this group, and the three did well—probably from luck possibly because a wider sympathectomy was done. The resection included the presacral plexus, lower two lumbar ganglia on each side, inferior mesenteric and iliac nerves. Surgically more radical, this seems less radical physiologically than intra-aortic alcohol.

CHAIRMAN ALMY: Unless there is some more business to come before this Section, the meeting stands adjourned.

OBSERVATIONS ON THE SYMPTOMATOLOGY OF CHOLELITHIASIS*

With Special Reference To Vomiting

BY ROBERT ZOLLINGER, M.D.,† AND EDMUND YOUNG, M.D.†

WE became interested in the symptomatology of cholelithiasis after studying several patients whose pain varied from the typical syndrome of biliary colic. Since the pain is often the result of overdistention of the gallbladder or major bile ducts by a calculus, we attempted to simulate this by mechanical means in conscious patients. By such a method we hoped to study the symptoms produced by distention of the gallbladder as compared with distention of the major extrahepatic ducts. In this report a clinical study, based on our experimental findings, has been undertaken in an effort to evaluate the symptoms of cholelithiasis in relation to the location of the offending calculus.

Our observations consisted of the mechanical distention of the gallbladder or common duct in six patients.¹ Under a short gas oxygen anesthesia or local infiltration of novocain the stones were removed from the gallbladder or common duct and a sterile balloon was inserted which could be distended and the pressure recorded. When the patient had recovered sufficiently from the anesthesia to answer all questions intelligently the gallbladder or common duct was

distended. Distention of the gallbladder produced a feeling of indigestion or deep epigastric discomfort without the usual referred pain to the back or discomfort in the right hypochondrium. Nausea and vomiting did not occur regardless of the degree of distention. Distention of the common duct produced a more severe epigastric distress but again pain was not referred to the back. Inspiratory distress was characteristic of distention of either viscus. The chief difference between distention of the gallbladder and of the common duct was the occurrence of nausea and vomiting with the latter.

The significance of these observations was then determined from a study of the clinical histories of three hundred cases previously operated upon in the Peter Bent Brigham Hospital for cholelithiasis. Particular reference was made to the location of their initial pain and the occurrence of involuntary vomiting. These cases were divided into three groups of one hundred cases each. The first group included only patients with cholecystitis and cholelithiasis who had never been jaundiced and in whom no evidence of cystic or common duct calculus could be found at operation. As far as could be determined in this control group the ducts had not been distended by a calculus and the symp-

disc is maintained by a marginal rim on the end surface of the vertebra.

The construction of the nucleus pulposus gives to the spinal column its resilient quality. Acting like a spring which is, at the same time, equally under pressure and compression, this elastic semi fluid mass takes from the bony surfaces the force of blows and distributes the shock of sudden jars, lessening their effect upon the nervous system. Any pathology, therefore, which interferes with the proper function of the disc as a shock absorber may give symptomatology in this region. Schmorl, commenting on the frequency with which changes in the intervertebral discs occur, says that "with increasing age they become so frequent that after the middle of the sixth decade it is almost impossible to find a spine in which all the intervertebral discs are normal." That such alterations may not always be found in those doing hard physical labor but may appear in severe form in brain workers suggests that disturbances in metabolism and endocrine disorders may, at times, enter the picture. Schmorl has differentiated three forms which changes in the discs may assume: (1) a drying of the tissue of the disc, (2) an increased moisture in the tissue, inducing gross fissure formation and ultimately destruction of the disc, and (3) the occurrence, primarily, of fissures in the discs. In the drying process the volume of the disc is decreased and the tissue becomes brittle and crumbly.

Pathology in the disc may also assume the form of a displacement of the intervertebral tissue, which may protrude in nodular excrescences through fissures in the cartilaginous plates. Through the tension of the nuclear tissue these small villi are pressed into defects in the cartilaginous plates and thence into the spongiosa of the vertebral bodies. If they occur on the posterior surface of the intervertebral disc, they may extrude into the spinal canal possibly irritating the spinal cord and even at times inducing paralysis. Such nuclear hernias or prolapses may cause proliferation of cartilaginous tissue, which may calcify and finally become ossified. Prolapses of the nuclear tissue in young people may lead to kyphosis. In adults they are not conducive to curvature, first because the cartilaginous nodules develop, for the most part, only in a single disc, secondly, because much less tissue prolapses on account of the decreased expansion in the region of the nucleus, and thirdly, because the growth of the vertebral bodies has ceased and therefore the kyphosis seen in youth through ossification disturbances can no longer take place. The most significant changes are secondary to nodule formation and consequent upon the resulting destruction of the nucleus and the obliteration of the joint space. The two cartilaginous plates are then brought into juxtaposition.

Keyes and Compere⁴ remark that "if only a small portion of the nucleus pulposus is extruded the function of the disc may not be seriously affected, but the extrusion of even small amounts may lead to an earlier than usual dehydration of the disc and therefore diminished function at an earlier age. Such small ruptures may thus be a predisposing etiological factor in the development of arthritis of the spine later. If so much fluid escapes that the nucleus pulposus is destroyed, the axis of motion is shifted posteriorly to the articular facets and the weight of the body is transferred to the lateral or anterior portion of the vertebral bodies."

Weaver⁵ believes that rupture of the nucleus pulposus would require considerable force and that, consequently, rupture due to sudden

FIG 1. Dissection of lumbo-sacral area.

trauma is probably rare. Of more frequent occurrence, on the other hand, is narrowing of the disc due to mild continuous trauma, such as faulty posture, which throws a continuous strain on the lumbosacral junction.

Calvé and Galland note, among the changes which may take place in the intervertebral discs, calcification of the nucleus. In this condition the cells of the nucleus are necrosed and the fibrous tissue destroyed by calcareous deposit. A satisfactory explanation for this calcification, they say has never been given. These authors, like Schmorl, have observed herniation of the nucleus pulposus into fissures in the cartilaginous plates, with resultant rarefaction and destruction of the bone.

On the other hand, destruction of the intervertebral discs may be secondary to pathological conditions in the vertebral bodies as in os

chronic cholelithiasis and chronic cholecystitis without a history of jaundice was 47.2 years. This average was almost identical with the one hundred cases of acute cholecystitis which was 47.1 years. The patients with common duct stone averaged about six years older, which suggests that the longer the patient carries the stones the greater the chance of a calculus escaping into the common duct. This is an argument in favor of an earlier operation in cases of cholelithiasis. The period of hospitalization was considerably longer in the group of acute cholecystitis (21.7 days) and common duct stone (22.8 days) than in the uncomplicated cases (16.7 days).

The mortality figures demonstrate the seriousness of the complications in cholelithiasis. It so happened that no deaths occurred in the uncomplicated cases, although a few pulmonary complications and wound infections did occur. The mortality rate of the one hundred cases of acute cholecystitis was five per cent. A cholecystostomy was done in eight of the one hundred cases. Sepsis was the etiological cause of death in a greater number than pulmonary complications in this group. The mortality rate of the one hundred cases of proved common duct stone was twelve per cent. We feel, however, that careful exploration of the common duct in itself adds little to the mortality rate. The method described by Cheever² was usually employed. Pulmonary complications accounted for seven of the twelve deaths in the latter group.

SUMMARY

Observations are recorded following the distention of the gallbladder or common duct in six patients operated upon for cholelithiasis. The cardinal findings of clinical importance were as follows: (1) Failure by this method to reproduce the usual referred pain to the back, (2) the consistent complaint of inspiratory distress, (3) the absence of vomiting when the gallbladder was distended and the prominence of this symptom when the ducts were distended.

The importance of these findings was tested by a study of the records of three hundred cases of cholelithiasis consisting of one hundred cases of cholelithiasis and chronic cholecystitis with a negative history for jaundice, one hundred cases of acute cholecystitis and one hundred cases of proved common duct stone.

Our observations, which showed that vomiting followed distention of the common duct, were in accord with the clinical findings that distention of the biliary ducts, as by a calculus, produced a high percentage of involuntary vomiting as compared with calculi within the gallbladder. We are suspicious of a calculus in the cystic or common duct in cases having pronounced involuntary vomiting and we believe it should be considered in the group of indications for exploration of the common duct.

FURTHER CASE STUDIES OF LUMBO-SACRAL PATHOLOGY WITH CONSIDERATION OF THE INVOLVEMENT OF THE INTERVERTEBRAL DISCS AND THE ARTICULAR FACETS

BY CHARLES E. AYRES, M.D.*

INTEREST in the conditions conducive to painful symptoms in the lower back has by no means abated since our last contribution to the subject in 1929¹. On the contrary, it has increased in considerable degree and so much has the literature been enlarged that one is made increasingly aware of the multitude of possibilities for pathology in this region. Our conclusions in 1929, from the study of thirty-six cases, were that the anatomical structures most concerned in low-back pain were the intervertebral discs, the articular facets, and the 5th lumbar nerve. In the intervening five-year period every angle of the etiology has been investigated. Particularly painstaking researches into the minutest details of the anatomy, normal and pathological, and the physiology of the intervertebral spaces, have been carried on by the German school headed by Schmorl². As so aptly phrased by Calvé and Galland³, "a new chapter in vertebral pathology has been disclosed the

pathology of the intervertebral disc." Intimately connected with this are destructive processes in the intervertebral articulations and the implication of the 5th lumbar nerve root.

THE INTERVERTEBRAL DISCS

The intervertebral disc consists of the nucleus pulposus, a central flattened lens of loose fibrous tissue, made up of cartilaginous cells and containing synovia-like fluid under pressure. This central gelatinous mass is held in place by a strong, elastic fibrocartilaginous envelope, the annulus lamellosus, the fibres of which are in continuity with the fibres forming the periphery of the vertebral surfaces. The end surfaces of the vertebrae are covered by a thin layer of cortical bone, quite compact in the center over the nucleus pulposus and more porous peripherally. Over this cortical bone lies the cartilaginous plate, composed of hyaline cartilage, which ends abruptly anteriorly and laterally by abutting the bony epiphyseal ring. A firm connection between the body of the vertebra and the intervertebral

*Ayres, Charles E.—Orthopedic Surgeon, Memorial Hospital, Worcester. For record and address of author see "This Week's Issue," page 730.

tilage may be found in the articular cartilage of these facets. This degeneration may go on to complete loss of the cartilaginous surface and irregular hypertrophy of the margins similar to that encountered in the advanced stages of degeneration or hypertrophic arthritis of other joints. With narrowing of the intervertebral discs there is overriding of the surfaces of the facets and with this abnormal contact traumatic arthritis is set up. Ghormley believes the sciatic pain in these cases to be more likely caused by pressure on the nerve or nerve sheath excited by the facet than by the intervertebral disc

FIG. 3. Cross section of spine at lumbosacral joint showing intimate relation which fifth lumbar nerve root bears to facets and lumbosacral cartilage.

The degree to which the facet may be involved in any inflammatory process in the intervertebral spaces and the character of the changes are strikingly brought out by the pathological report on a specimen of tissue from the lumbosacral facets in one of our cases (No. 78), which was as follows: "Sections of the soft tissue show a dense stroma with some round cell infiltration and much fibrosis change. Some areas show calcification and bone formation. Sections of the decalcified bone show moderate round cell infiltration and many fat cells, evidence of chronic inflammatory changes. Diagnosis: Chronic inflammatory tissue, beginning calcification and ossification." (Dr. P. Beregoff.)

Willis¹² points out the frequency with which anomalies of the vertebrae occur and says the last presacral vertebra shows a tendency to variability in its transverse processes and articula-

tions with the sacrum. Junghans¹³ calls attention to the fact that the 5th lumbar is not always the last presacral vertebra as there may be an anomalous number of vertebrae with displacement of the various segments of the column. All such anomalies predispose the lumbosacral region to pathology.

Banstrup¹⁴ emphasizes the importance of the spinous processes in painful conditions of the back. "The lumbar vertebrae form," he says, "a mutual system of leverage with the axis posterior to the middle of the vertebrae. Therefore, the spinous process is the short lever arm in the system. Under special conditions they may be pressed against each other with great force, the soft parts between them sharing in this process. If this compression is continued, the spinous processes themselves become the site of osteoarthrotic pathological changes. As a result may be seen obliquely placed spinous processes, faceted contact surfaces, osteosclerosis of the bony tissue surrounding the contact surfaces, anomalous contact surfaces, osteophytes at the ends of the articulations, 'mouse' formation and ankylosis. In attempting to compensate for this there is constant strain on the musculature." The number of cases in our own series in which the spinous processes were involved was too small for us to speak with much authority on this point.

CLINICAL FINDINGS

Since our report in 1929, a series of sixty-three new cases have been operated upon. A study into the symptomatology of these patients (nearly twice the number reported upon previously) substantiates the statements then made in regard to the clinical findings in these cases of lumbosacral pathology. These are as follows: usually a list to one or the other side, marked tenderness at the lumbosacral junction, although palpation may be difficult and the tenderness masked in muscular patients with severe contraction of the erector spinae in most cases, distinct tenderness over the gluteus medius just below the crest of the ilium, in some instances, tenderness in back of the trochanter, in the region of the gluteal fold, burning pain along the outside of the thigh corresponding to the tensor fasciae femoris and in severe cases, burning pain involving the outside of the calf and extending beneath the external malleolus and down to the dorsum of the foot. Whether there is atrophy depends upon the severity of the involvement as well as its duration. In our complete series of ninety-nine cases we found considerable variation in the duration of the symptoms. One patient (reported in our first series) complained she had had her symptomatology "all her life." The longest stated period was thirty-five years, the shortest, four weeks, and the average a fraction over two years.

teomalacia, generalized osteitis fibrosis or senile osteoporosis. Schmorl says that while primary metastatic affections of the healthy intervertebral discs of adults cannot occur because the discs have no blood supply and therefore cannot be infected through the blood stream nevertheless suppurations in the region of the disc may attack and destroy it.

Bohmig⁶, through his study of the blood supply to the intervertebral discs in the embryo and in youth, is convinced that the growing disc is much more intimately concerned in the circulation of the blood and in metabolism than has previously been recognized. They may share, therefore, up to the beginning of the twentieth year, in all general diseases of the body, in disturbances of metabolism and infectious blood diseases (bacteremia, sepsis typhus, etc). So it is realized that theoretically all metastatic processes may be present in the intervertebral discs although practically Schmorl has not yet been able to produce such findings in all of his considerable material. There is, Bohmig believes, a possibility of postinfection diseases of the intervertebral discs in the young after grippe and staphylococcal and streptococcal infections. Bohmig also found that the formation of cartilaginous nodules, as described by Schmorl, most often took place at the site of the present or former blood-vessel canals. This author also accounts for anomalies in the form of the nucleus pulposus by the fact that the intervertebral chordal segment is the matrix of the nucleus pulposus and gross and microscopic anomalies of form of the chorda have an extraordinary significance in the development of the nucleus pulposus. Every displacement of the parts of the notochord, every segmentation of its cell complex leads to a diminution of the material for the formation of the gelatinous mass and therefore anomalies in the form of the nucleus pulposus follow. This is most important as regards the statics and dynamics of the vertebrae.

THE ARTICULAR FACETS

So closely related are the anatomical structures in the intervertebral spaces that one part, or all, may share in the destructive process. Secondary to thinning of the intervertebral discs there may be changes in the articular processes of the vertebrae. Keves and Compere were able to produce experimentally in animals complete disappearance of the disc and sclerosis with spur formation andipping of the adjacent bone surfaces by injury to the nuclear material. In every instance where nucleus pulposus material had been permitted to escape, there was definite narrowing of the intervertebral disc and when most of the nucleus was curetted out, the adjacent vertebrae showed

early changes of typical hypertrophic or osteoarthritis of the spine and fibrosis of the material remaining in the space previously occupied by the nucleus pulposus. Williams⁷ says that with herniation of the nucleus pulposus and loss of the intervertebral space, owing to settling of the vertebrae, there is, in turn, partial subluxation of the articular facets and diminution in the diameter of the intervertebral foramina. The axial force and pivoting which formerly came on the resilient nucleus pulposus must now fall on the inelastic superior surface of the first sacral segment. As motion

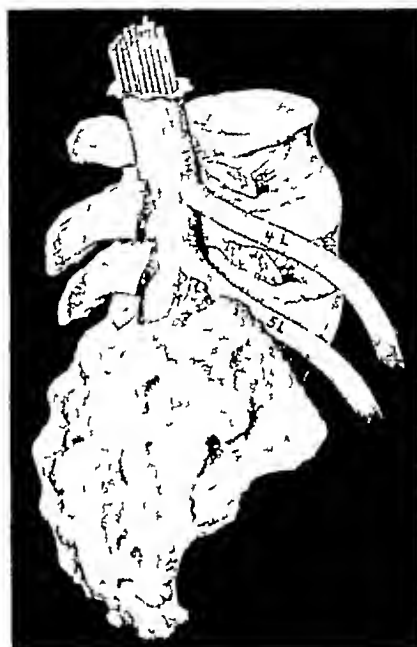

FIG. 2 Lumbo-sacral area showing relation of fifth root to lumbo-sacral facet

continues, a pressure atrophy results and the body surfaces may be scarred and narrowed.

In a paper by Williams and Yglesias⁸ they divide their cases into two classes: (1) those in which there is a complete loss of the disc and (2) a group showing only narrowing of the disc posteriorly. In the second class, they find the mechanical alteration in the region of the articular facets and foramina with consequent irritation of the 5th lumbar nerve root, is as great, if not greater, than in the first group. With loss of the intervertebral disc and subluxation, the inferior facets of the 5th lumbar vertebra move down and backward, thereby closing off the foramina and causing pressure on the 5th lumbar nerves.

Ghormley^{9, 10, 11} mentions the fact that the articular facets are the only true joints in the spinal column, a point brought out by the writer in 1929. Hyaline cartilage covers their surfaces and synovial membrane lines their articular capsules. The degenerative changes, therefore, which are characteristically seen in hyaline car-

tilage may be found in the articular cartilage of these facets. This degeneration may go on to complete loss of the cartilaginous surface and irregular hypertrophy of the margins similar to that encountered in the advanced stages of degeneration or hypertrophic arthritis of other joints. With narrowing of the intervertebral discs there is overriding of the surfaces of the facets and with this abnormal contact traumatic arthritis is set up. Ghormley believes the sciatic pain in these cases to be more likely caused by pressure on the nerve or nerve sheath excited by the facet than by the intervertebral disc.

FIG. 3. Cross section of spine at lumbo-sacral joint showing intimate relation which fifth lumbar nerve root bears to facets and lumbo-sacral cartilage.

The degree to which the facet may be involved in any inflammatory process in the intervertebral spaces and the character of the changes are strikingly brought out by the pathological report on a specimen of tissue from the lumbo-sacral facets in one of our cases (No. 78), which was as follows: "Sections of the soft tissue show a dense stroma with some round cell infiltration and much fibrosis change. Some areas show calcification and bone formation. Sections of the decalcified bone show moderate round cell infiltration and many fat cells, evidence of chronic inflammatory changes. Diagnosis: Chronic inflammatory tissue, beginning calcification and ossification." (Dr. P. Boregoff.)

Willis¹² points out the frequency with which anomalies of the vertebrae occur and says the last presacral vertebra shows a tendency to variability in its transverse processes and articula-

tions with the sacrum. Junghans¹³ calls attention to the fact that the 5th lumbar is not always the last presacral vertebra as there may be an anomalous number of vertebrae with displacement of the various segments of the column. All such anomalies predispose the lumbosacral region to pathology.

Baastrup¹⁴ emphasizes the importance of the spinous processes in painful conditions of the back. "The lumbar vertebrae form," he says, "a mutual system of leverage with the axis posterior to the middle of the vertebrae. Therefore the spinous process is the short lever arm in the system. Under special conditions they may be pressed against each other with great force, the soft parts between them sharing in this process. If this compression is continued, the spinous processes themselves become the site of osteoarthritis, pathological changes. As a result may be seen obliquely placed spinous processes, faceted contact surfaces, osteosclerosis of the bony tissue surrounding the contact surfaces, anomalous contact surfaces, osteophytes at the ends of the articulations, mouse formation and ankylosis. In attempting to compensate for this, there is constant strain on the musculature." The number of cases in our own series in which the spinous processes were involved was too small for us to speak with much authority on this point.

CLINICAL FINDINGS

Since our report in 1929, a series of sixty-three new cases have been operated upon. A study into the symptomatology of these patients (nearly twice the number reported upon previously) substantiates the statements then made in regard to the clinical findings in these cases of lumbosacral pathology. These are as follows: usually a list to one or the other side; marked tenderness at the lumbosacral junction, although palpation may be difficult and the tenderness masked in muscular patients with severe contraction of the erector spinae; in most cases, distinct tenderness over the gluteus medius just below the crest of the ilium; in some instances, tenderness in back of the trochanter in the region of the gluteal fold, burning pain along the outside of the thigh corresponding to the tensor fasciae latae, and in severe cases, burning pain involving the outside of the calf and extending beneath the external malleolus and down to the dorsum of the foot. Whether there is atrophy depends upon the severity of the involvement as well as its duration. In our complete series of ninety-nine cases we found considerable variation in the duration of the symptoms. One patient (reported in our first series) complained she had had her symptomatology "all her life." The longest stated period was thirty-five years, the shortest, four weeks, and the average a fraction over two years.

FIFTH NERVE ROOT INVOLVEMENT

The clinical findings, as stated in our previous paper, are adequately accounted for by the anatomical position of the 5th lumbar nerve root and the distribution of its branches. Lying, as it does, between the lumbosacral intervertebral disc and the lumbosacral articular facets, it is liable to involvement in any inflammatory process which attacks either the disc or the facets. Pain then occurs along the course of its branches, the 5th root fibres to the gluteus medius and gluteus minimus giving pain just below the crest of the ilium and in the region of the trochanter and outer aspect of the buttock the fibres to the tensor fasciae latae causing pain along the outside of the thigh, the fibres to the semitendinosus, semimembranosus and biceps giving the symptomatology down the back of the thigh, and the fibres to the crural groups of muscles involving the calf and dorsum of the foot. Continued study of the subject impresses upon us even more forcibly the frequency with which pain radiated down one leg or both. In our entire group of ninety-nine cases, eighty-one patients had pain in the legs, fifty-eight of these in one leg or the other and twenty-three in both legs. Putti¹⁵ has called this type of sciatica which is secondary to some abnormal condition in the spinal column "vertebral sciatica" and says that in 345 cases of lumbar arthritis examined during ten years at the Institute Rizzoli, sciatica was present in 231. Williams notes that the quadratus lumborum and multifidus spinae receive part of their innervation from the 5th lumbar nerve through the posterior perforating branches. This may be an important factor, he says, in muscle spasm of the lower part of the back and, associated with reflex spasm of the psoas muscle, probably explain the spinal rotation and list seen in arthritic irritation. The earliest symptoms of nerve root irritation are likely to be gluteal pains and tenderness, usually interpreted as sacroiliac pathology, but which, he believes, are due to irritation of the superior gluteal nerve through the 5th lumbar segment. The fibers of the superior gluteal nerve are peripherally placed within the 5th lumbar nerve root and are therefore the first to register irritation.

TREATMENT

We have continued to use the Hibbs fusion operation, the technique of which is outlined in our previous article. The results have been almost uniformly excellent (as will be seen in the analysis of our cases), and this operation has the advantage of keeping the patient hospitalized for only ten days or two weeks, at the end of which time, a plaster jacket is applied in extension with a pelvic belt having two straps so as to rotate the pelvis posteriorly and bring the sacrum into proper alignment with the spi-

nal column, that is, to make the superior or bearing surface of the sacrum as horizontal as possible. The patient is then allowed to go home and wears the plaster jacket for six weeks, when it is removed and a spring back brace which extends up to include the shoulders is fitted to him.

In none of our cases has facetectomy been deemed necessary. To attempt this step at the time of the fusion operation is to encounter the danger of involving the 5th nerve root in a mass of callus formation, thus nullifying the results of the fusion. On the other hand, if facetectomy is performed as a secondary operation, it becomes a difficult procedure to reach the facet after the fusion has formed.

Williams and Yglesias have performed the fusion operation in thirteen cases within eighteen months with complete relief of symptoms in all the cases but one. In this case pain persisted along the course of the left sciatic nerve, which, it was felt, was due to constriction of the foramen between the 5th lumbar and 1st sacral vertebrae, with irritation of the 5th nerve segment. Therefore, at a second operation the left inferior articular facet of the 5th lumbar vertebra was removed and also the sacral facet, and the nerve freed from surrounding tissue from the point at which it emerged from the neural canal. The patient made a perfect recovery.

ANALYSIS OF CHARTED CASES

Ninety-nine cases have been studied, which may be divided as follows:

Cases with thinning of the disc (shown by x-ray)	59
Cases with lumbosacral involvement without discernible thinning of the disc	31
Spondylolisthesis	6
Sacralization	1
Impingement of spinous process	2
	99

Of the fifty-nine cases with thinned discs, fifty-two had pain referred to the legs and seven had no pain in the legs. Of the lumbosacral cases without thinning of the disc, thirty-one in all, twenty-three patients complained of pain in the legs and eight did not. The patient with sacralization did not have leg pain and the two patients with impingement of the spinous process complained of no pain in the legs.

We have been able to follow ninety-three of our patients and have the subjoined data:

1 patient is well at the end of a 10 year period	
4 patients are " " " " " " " " " " " "	9
14 " " " " " " " " " " " "	8
17 " " " " " " " " " " " "	7
3 " " " " " " " " " " " "	6
15 " " " " " " " " " " " "	5
19 " " " " " " " " " " " "	4
1 patient is " " " " " " " " " " " "	3
6 patients are " " " " " " " " " " " "	2

80 patients

Eighty of our patients, therefore, have been heard from and are well from two to ten years after operation.

Of the remaining nineteen patients, one has died, one was well for eight years and then developed Paget's disease, one was well for a year and a half and after that could not be traced, six have been lost track of entirely, and ten still complain of pain.

Of the ten patients still complaining of pain, four are patients who showed thinning of the disc by x ray (Nos 28, 30, 55 and 96 on the chart), four are lumbosacral cases with no thinning of the disc discernible by x ray (Nos 37, 42, 46 and 51 on the chart), and two are cases of spondylolisthesis (Nos 47 and 83 on the chart).

Two of these ten patients reported for study, one a lumbosacral case without thinning of the disc (No 37) and one (No 55) with intervertebral disc thinning. Case No 37 was found to have solid fusion but had a large ventral hernia recurring in the scar of a previous abdominal operation. From the examination it appeared that her back symptoms were related to this condition. Case No 55 was operated upon in 1928 and remained well for four years when the symptoms recurred following heavy lifting. He did not have a return of the sciatic symptoms and x ray showed a probable pseudoarthrosis.

CONCLUSIONS

A group of ninety nine patients with lumbosacral symptomatology has been analytically investigated. The end results are known in ninety three cases and in eighty the results of operation have been excellent. The earliest of these cases was operated on in 1924 and thirty six of them previous to 1929, so that we have the results of at least a five year period in all these earlier group and in some cases the postoperative period is as long as ten years. In addition, we have the results in a larger group of sixty three cases, some of them operated upon four years ago. We feel, therefore, that we have convincing evidence of the soundness of our theory of the etiology of lumbosacral backache and the

efficacy of the Hibbs fusion operation as the preferred mode of treatment. Our further study of the subject, over a period of five years since 1929, has served to corroborate the conclusions drawn at that time, namely, that

- (1) A destructive process of the lumbosacral cartilage is a common finding in cases of low back pain.
- (2) An arthritic involvement of the lumbosacral facets may alone cause symptoms of back pain and sciatica.
- (3) Ankylosis is indicated.
- (4) The results of fusion by the Hibbs method are satisfactory in cases that do not respond to conservative treatment.

TRICHOBEZOAR*

BY ALFRED HURWITZ, M.D.†

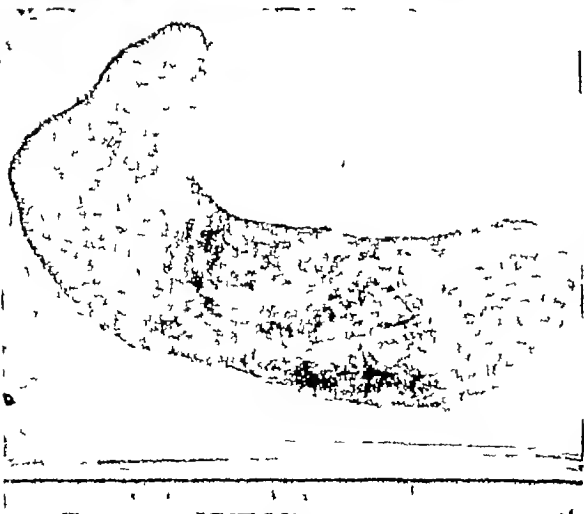

WE have recently had the opportunity of studying and operating on a case of hair ball of the stomach. Because of the rarity of this condition, this case is reported in full.

G. P. eleven year old female was admitted to the Beth Israel Hospital October 6 1934. During the preceding two years the patient had had dull epigastric pain with an acute exacerbation three days before admission, accompanied by nausea and vomiting of unchanged food particles. Intermittent, sharp epigastric pain persisted up to the time of admission. The past history revealed that the patient had always been underweight and had had several intercurrent infections, namely bronchopneumonia at two and one-half years of age, pharyngitis at seven years which confined her to bed for seven months.

Physical examination revealed a temperature of 100° F rectally pulse 84 respirations 20 and weight

From the Surgical Service of the Beth Israel Hospital. Hurwitz, Alfred—Intern, Boston Lying In Hospital. For record and address of author see "This Week's Issue," page 723.

55 pounds. The patient was a frail, slightly undernourished girl with obvious pallor. She had an apparently normal mental development. Her breath was quite foul. The scalp showed some scaly crusts and a sparsity of hair. Abdominal examination revealed a mass in the left upper quadrant which was about 8 cm long and 4 cm wide in the shape of a J. The mass was nontender, freely movable and moved with respiration. Clinical pathology revealed a red blood count of 4,250,000 Hb 8 per cent and a white count of 10,600. Hair was observed in the stools twice preoperatively. A G I series on October 9, 1934 revealed a large atonic stomach with marked pylorospasm and a mottled appearance with some residue after six and twenty-four hours. A flat x-ray film of the abdomen revealed displacement of the transverse colon downward.

On October 17 the patient was operated on by Dr C G Mixer and on exposing the interior of the stomach through a two inch vertical gastrotomy incision a hair ball was observed forming a com-

plete cast of the stomach. This was removed and the incision closed. The patient made an uneventful convalescence and was discharged November 2, 1934.

COMMENT

The last complete review of trichobezoar was written by Maes¹ in the *Annals of Surgery*, October, 1928, at which time he reported 119 cases. Other complete studies were published by Butterworth² and Matas³.

This condition occurs usually in young girls who display a normal mentality but a perverted appetite. The following are aids in diagnosis: (1) age and sex of the patient, (2) personal habits, for example, hair chewing, (3) careful search of the stools for hair and (4) x-ray studies which reveal a mobile mass conforming to the shape of the stomach and showing a mottled appearance on the six-hour plate. The physical findings and history in this case are quite typical of the disease. It should be emphasized that at the time of operation a careful search for multiple hair balls should be made inasmuch as one or more may be lodged in the small intestine. The largest trichobezoar, which was reported by Davies, is reputed to have weighed six and one-half pounds.

Phytobezoars or food balls are usually composed of coconut, vegetable or salsify fibres, but most commonly, of persimmon seeds. The symptoms are more severe with phytobezoar than with trichobezoar and are characterized by a severe gastroenteritis with abdominal pain, fever, and occasionally occult blood in the stools and in the vomitus. Moreover, the patient harboring the food ball is predominantly of the male sex and most commonly of the age group between forty and sixty years. Ulceration with subsequent perforation and peritonitis is more frequently observed with the phytobezoar. The operative mortality of bezoars in general has been estimated to be about four per cent by Maes and the causes of death are attributable to intestinal obstruction, or perforation followed by peritonitis and inanition.

SUMMARY AND CONCLUSIONS

A complete history of another case of trichobezoar has been reported. The differentiating features of trichobezoar and phytobezoar have also been presented.

TRACY B. MALLORY, M.D., Editor

CASE 21411

PRESENTATION OF CASE

A fifty-two year old single Canadian bookkeeper entered complaining of shortness of breath upon exertion and change in her bowel habits.

One year before entry she had a severe attack of loose, watery, mucus-containing stools several times a day which cleared up in about ten days. Since then she had been slightly constipated and her stools had been small in caliber. Three and a half months before entry she had a similar but less severe attack. At this time she had a few night sweats but had had none since. Ten days later she noticed the onset of shortness of breath upon slight exertion. There was no cough or sputum. At that time she entered a hospital where her chest was tapped. She returned two weeks later to that hospital for another chest tap. During the six weeks before entry she had three more paracenteses. Approximately two months before entry she noticed abdominal swelling and a sense of pressure in the epigastrium which was more marked when sitting. This abdominal swelling had decreased with salyrgan treatment. Her appetite had decreased during this illness but had improved somewhat during the past month. At the time of admission she felt quite comfortable. Her chest had been tapped three days before entry and salyrgan had decreased her abdominal swelling.

Her family history is non-contributory.

Nine years before entry she was "run-down," due to hard work and long hours. At this time she noticed blood in her mouth on several occasions and on her pillow in the morning. A physician told her that she had a spot on her lung and she remained at home for two and a half months. Re-examination at that time was said to have been normal. The remainder of her past history is non-contributory. Her menopause had occurred about five years before entry.

Physical examination showed a well-developed and fairly well-nourished woman lying flat in bed. The right chest expanded very little and

was flat to percussion both anteriorly and posteriorly. The breath sounds were very distant. There was no fremitus. The upper half of the left chest was hyperresonant and the breath sounds were prominent. The heart was displaced to the left. The sounds were of good quality. The abdomen was soft and distended and showed a fluid wave and shifting dullness.

The temperature was 98°, the pulse 100. The respirations were 20.

Examination of the urine was negative except for a slight trace of albumin. The blood showed a red cell count of 4,230,000 with a hemoglobin of 65 per cent. The white cell count was 13,600, 78 per cent polymorphonuclears. The sputum was thin, mucoid and contained rare Gram positive cocci. Four sputum examinations were negative for tubercle bacilli. The stools were soft, light brown in color and showed consistently negative guaiac tests. The nonprotein nitrogen of the blood was 39 milligrams per 100 cubic centimeters, the chlorides 95 cubic centimeters of N/10 Cl. The serum protein was 7.1 per cent. A Hinton test was negative.

X-ray examination of the chest showed that the entire right lung field was obliterated by dense homogeneous dullness which extended up to the first interspace. The shadow of the heart showed only a slight amount of displacement. There was no evidence of metastatic disease in the bones or ribs. A gastrointestinal series was negative.

On the third day 2,300 cubic centimeters of clear yellow fluid was withdrawn from the right pleural cavity and replaced by 1,600 cubic centimeters of air. The fluid had a specific gravity of 1.019. The cell count could not be determined because the fluid was clotted when received. A smear showed many red blood cells and lymphocytes. A culture gave Gram negative and positive bacilli. A guinea pig inoculated with this fluid was negative for tuberculosis.

An x-ray of the chest following paracentesis and the introduction of air showed no lung tissue in the upper two-thirds of the right lung field. There was a straight fluid level extending about two inches above the diaphragm. The findings were those of hydro-pneumothorax with complete collapse of the right lung.

On the twelfth day about 5 liters of yellowish clear fluid was removed from the abdomen. A cell count gave 725 red blood cells, 20 white blood cells and 155 epithelial cells. A culture showed no growth. Following this paracentesis an irregular mass, presumably the liver, was easily felt in the right upper quadrant. On pelvic examination a large, hard, tender, retroverted and recessed uterus was found. On the fourteenth day an exploratory laparotomy was performed.

Following operation the patient's condition remained the same except that there was no ap

parent accumulation of either abdominal or chest fluid. She was discharged three weeks after operation at which time practically all her chest and abdominal fluid had disappeared.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. MILLER: I have read this over and the logical diagnosis, it seems to me, is so obvious and simple that I cannot help suspecting Dr. Mallory of having dug a pit for me to fall into. We shall see.

Shortness of breath occurred, for which she had to have her right chest tapped, and that was done several times before she came to this hospital. Also, shortly before her entry, she noticed her abdomen getting larger. Therefore, we have to find one cause for fluid in the right chest and fluid in the abdomen.

Nine years before entry she was thought to have tuberculosis which may have been moderately active but it presumably became quiet, if not entirely healed. However, one has to consider tuberculosis in making the final diagnosis.

When she came in here it was perfectly obvious that the right side of the chest was filled with fluid, pushing the heart over to the left, and there was also fluid in the abdomen but no fever.

The various laboratory data are not particularly helpful until we get down to the examination of the fluid. The x-ray shows fluid but nothing else.

From the right chest there was withdrawn this fluid which clotted very quickly and contained red blood cells and lymphocytes. A guinea pig was inoculated and the result was negative. Then later on the abdomen was tapped and five liters of fluid containing blood cells and epithelial cells was withdrawn. The fluid showed no growth on culture.

The next matter of importance is the pelvic examination which you see demonstrates a large, hard, tender, retroverted and recessed uterus.

The outstanding features in this case are fluid in the chest containing blood cells and fluid in the abdomen containing blood cells. To me blood cells in an aspirated fluid mean cancer. I do not think there is any logical reason to question that statement. I do not think that red cells would be found in a tuberculous exudate and I am sure they would not be found in a transudate resulting from disease of the heart or kidneys. Therefore, we will say that the underlying disease is cancer and, although it first appeared in the chest, it is logical to assume that it originated in the abdomen, that is, although her symptoms first occurred as a result of fluid in the chest, this cancer arose in the abdomen. What kinds of cancer in a female cause fluid, ascites, and may metastasize to the chest? First, carcinoma of the ovary. Nineteen times out of twenty it would be carcinoma of the ovary that would cause the picture

which we are studying here. Once in a great while cancer originating in some other organ will result in a general carcinomatosis and ascites and in the past few years I have seen a substantial number of such cases in which even with a large incision in the abdomen, where one could both see and feel, it has been entirely impossible to determine where the growth had its origin. The last case of that nature which I saw a short while ago was in a young man. Unfortunately we could not get a postmortem but he had a picture just like this. Had it been a woman I certainly would have said carcinoma of the ovary. In this case the pelvic examination notes that the uterus is slightly enlarged, hard and retroverted, but I am inclined to disregard that because I believe she had a carcinoma of the ovary and for one reason or another it might not have been clearly felt at that examination. Therefore, I shall say, and I hope I am not falling into a pit, that she had primary papillary adenocarcinoma of the ovary with general carcinomatosis, metastases in the liver, which I neglected to mention, and metastases in the right pleural cavity.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES: The films in this case present the characteristic picture of a large amount of fluid in the right pleural space. The heart is displaced and the lung markings have disappeared. After tapping we see the pleural space filled with air. If this patient had extensive metastases to the lung sufficient to produce a bloody pleurisy it is rather strange that the whole lung should have collapsed down to a mass no larger than is seen here and that there are no nodules visible in the parietal pleura. In other words, this looks now like an ordinary pneumothorax with fluid. I think that it is not impossible that this patient has metastases to the lungs but I certainly wonder if the fluid did not come from below the diaphragm rather than from some process in the chest.

DR. MILLER: What do you mean by that?

DR. HOLMES: That something ruptured through from the liver into the chest and in that way collapsed the lung. The heart shadow is not enlarged. We have no reason to suspect trouble with the vascular system. The gastrointestinal examination was said to be negative and I shall not attempt from this plate to dispute it. There is rather more than normal density in the pelvis. There may be, as Dr. Miller has said, tumor in the pelvis, but we have no positive proof.

CLINICAL DISCUSSION

DR. JOHN W. CASS: We were very much puzzled by this syndrome and felt that we had ruled out most of the common things that might give this picture. We thought we had ruled out tuberculosis. On questioning the patient it seemed

that there was little good evidence that she had really had it nine years before. She had a good deal of diarrhea at the time, had been overworking, lost a little weight and had a little blood in the mouth but no real hemoptysis. We ruled out any heart condition or kidney condition or Pick's syndrome which might have given this picture and because of the definite finding of tumor in the pelvis we felt that, since the patient was sent to this hospital for definite diagnosis and since she was in good condition and understood the whole situation and was willing to go through operation to determine the diagnosis, it was logical to put her through it. The diagnosis was malignancy of the ovary with metastases probably throughout the peritoneum and to the chest, although we thought that it was unusual to get complete absence of cancer cells in the fluid and to get this x ray picture.

DR. LELAND S. MCKITTRICK. As Dr. Cass said, our preoperative impression was pretty much as Dr. Miller had made it. We had not yet been able to make a positive diagnosis and as has been pointed out, the findings were not entirely characteristic of malignancy. Pelvic examination was not altogether satisfactory. She had a hard fixed uterus, a firm mass in the pelvis, the outlines of which I could not make out. Exploration was done, hoping to make a positive diagnosis, but without the slightest expectation that we were going to do her any good. The abdomen was opened and it was filled with straw-colored fluid then as in the taps. In the pelvis was a perfectly typical benign fibroma of the ovary. It was wedged in the pelvis but could be brought out easily. There were two or three small grayish areas on the peritoneum which looked almost like areas of pressure necrosis although they did not extend very deeply. The tumor was taken out but even then I had not the slightest idea that it was going to do any good. It is not too uncommon to find ascites with a benign tumor of the ovary but I cannot associate it with the fluid in the chest. Dr. Cass was deserving of no little credit in insisting upon removing the tumor, and it seemed satisfactory to take it out.

DR. TRACY B. MALLORY. Dr. Cass, will you tell us the outcome?

DR. CASS. This patient made an uneventful recovery and left the hospital about three weeks after the operation. She had been tapped previous to the operation, both her abdomen and chest, and there had been at the time of discharge no evidence of any reaccumulation of fluid. Without any specific therapy she had gained ten pounds in weight and had returned to her normal health. She has been followed since and a letter just recently received from her states that she is in the best of health, has gained twenty five pounds and has been working for six months at her occupation as a secretary.

There is only one other thing that Dr. Mc

Kittrick did not mention. The liver was very large, though otherwise perfectly normal as far as palpation could determine it, and the liver has decreased in size under the observation of the local doctor but can still be palpated. Dr. Meigs will probably say that this syndrome is not uncommon. There have been cases reported similar to this, three by Dr. Meigs in his book and one case that I found in the review of the literature in the last fifteen years of a case identical with this with complete recovery, so that in some way this tumor did cause this picture.

DR. MALLORY. As Dr. Miller suggested, I did lay a trap for him. I did not believe anyone would possibly come to any diagnosis in this case other than that of generalized malignancy and yet it would have been very easy to think that there was no use whatever in exploring such an evident and hopeless case. But the woman has completely recovered. Histologic examination of the tumor gave us no additional information. It was a perfectly typical benign fibroma of the ovary. This is by no means the first case of this type that we have found in this hospital.

DR. JOE V. MEIOS. I remember when I was with Dr. Graves at the Free Hospital that he said that a tumor in the pelvis with fluid in the abdomen was not necessarily a hopeless proposition. There are cases of fibroma of the ovary that are accompanied by a great deal of fluid that recover completely after removal of the tumor. I have seen quite a number and about thirty per cent have ascites. In going over the histories and pathological specimens of fibromas of the ovary three years ago I discovered three patients who had been studied on the medical wards and suspected of tuberculosis. They had pleurisy with effusion and were tapped two to six times each. Eventually a fibroma of the ovary was discovered and on removal of the tumor the ascites which they had and the pleural effusion cleared up. These three cases made me suspect that there ought to be a syndrome with ascites, pleural effusion and fibroma of the ovary. Dr. Cass's case is very similar to the other three, and two of our cases followed for five years and are free of any difficulty since their operations.

DR. AUBREY O. HAMPTON. Dr. Daniel Jones had a presumably benign tumor of the pancreas, a cyst, which was accompanied by pleurisy, and the fluid disappeared after exploration.

PREOPERATIVE DIAGNOSES

Tumor of the ovary, ? malignant.
Ascites, undetermined origin.
Gall stones

DR. RICHARD H. MILLER'S DIAGNOSIS

Papillary adenocarcinoma of the ovary with peritoneal metastases

PATHOLOGIC DIAGNOSIS

Fibroma of the ovary

parent accumulation of either abdominal or chest fluid. She was discharged three weeks after operation at which time practically all her chest and abdominal fluid had disappeared.

DIFFERENTIAL DIAGNOSIS

DR RICHARD H MILLER I have read this over and the logical diagnosis, it seems to me, is so obvious and simple that I cannot help suspecting Dr Mallory of having dug a pit for me to fall into. We shall see.

Shortness of breath occurred, for which she had to have her right chest tapped, and that was done several times before she came to this hospital. Also, shortly before her entry, she noticed her abdomen getting larger. Therefore, we have to find one cause for fluid in the right chest and fluid in the abdomen.

Nine years before entry she was thought to have tuberculosis which may have been moderately active but it presumably became quiet, if not entirely healed. However, one has to consider tuberculosis in making the final diagnosis.

When she came in here it was perfectly obvious that the right side of the chest was filled with fluid, pushing the heart over to the left, and there was also fluid in the abdomen but no fever.

The various laboratory data are not particularly helpful until we get down to the examination of the fluid. The x-ray shows fluid but nothing else.

From the right chest there was withdrawn this fluid which clotted very quickly and contained red blood cells and lymphocytes. A guinea pig was inoculated and the result was negative. Then later on the abdomen was tapped and five liters of fluid containing blood cells and epithelial cells was withdrawn. The fluid showed no growth on culture.

The next matter of importance is the pelvic examination which you see demonstrates a large, hard, tender, retroverted and recessed uterus.

The outstanding features in this case are fluid in the chest containing blood cells and fluid in the abdomen containing blood cells. To me blood cells in an aspirated fluid mean cancer. I do not think there is any logical reason to question that statement. I do not think that red cells would be found in a tuberculous exudate and I am sure they would not be found in a transudate resulting from disease of the heart or kidneys. Therefore, we will say that the underlying disease is cancer and, although it first appeared in the chest, it is logical to assume that it originated in the abdomen, that is, although her symptoms first occurred as a result of fluid in the chest, this cancer arose in the abdomen. What kinds of cancer in a female cause fluid, ascites, and may metastasize to the chest? First, carcinoma of the ovary. Nineteen times out of twenty it would be carcinoma of the ovary that would cause the picture

which we are studying here. Once in a great while cancer originating in some other organ will result in a general carcinomatosis and ascites and in the past few years I have seen a substantial number of such cases in which even with a large incision in the abdomen, where one could both see and feel, it has been entirely impossible to determine where the growth had its origin. The last case of that nature which I saw a short while ago was in a young man. Unfortunately we could not get a postmortem but he had a picture just like this. Had it been a woman I certainly would have said carcinoma of the ovary. In this case the pelvic examination notes that the uterus is slightly enlarged, hard and retroverted, but I am inclined to disregard that because I believe she had a carcinoma of the ovary and for one reason or another it might not have been clearly felt at that examination. Therefore, I shall say, and I hope I am not falling into a pit, that she had primary papillary adenocarcinoma of the ovary with general carcinomatosis, metastases in the liver, which I neglected to mention, and metastases in the right pleural cavity.

X-RAY INTERPRETATION

DR GEORGE W HOLMES The films in this case present the characteristic picture of a large amount of fluid in the right pleural space. The heart is displaced and the lung markings have disappeared. After tapping we see the pleural space filled with air. If this patient had extensive metastases to the lung sufficient to produce a bloody pleurisy it is rather strange that the whole lung should have collapsed down to a mass no larger than is seen here and that there are no nodules visible in the parietal pleura. In other words, this looks now like an ordinary pneumothorax with fluid. I think that it is not impossible that this patient has metastases to the lungs but I certainly wonder if the fluid did not come from below the diaphragm rather than from some process in the chest.

DR MILLER What do you mean by that?

DR HOLMES That something ruptured through from the liver into the chest and in that way collapsed the lung. The heart shadow is not enlarged. We have no reason to suspect trouble with the vascular system. The gastrointestinal examination was said to be negative and I shall not attempt from this plate to dispute it. There is rather more than normal density in the pelvis. There may be, as Dr Miller has said, tumor in the pelvis, but we have no positive proof.

CLINICAL DISCUSSION

DR JOHN W CASS We were very much puzzled by this syndrome and felt that we had ruled out most of the common things that might give this picture. We thought we had ruled out tuberculosis. On questioning the patient it seemed

ing in the history which could not be explained by tumor. In the mediastinum neoplasm could grow readily without making itself manifest until sufficiently large to interfere with circulation or respiration, the rapid increase of dyspnea and cyanosis could be due to sudden enlargement by hemorrhage or edema or to shift in location with change of the patient's position.

Physical examination, showing edema, dilated veins on the chest, and interference with flow of air in and out of the lungs, presents definite confirmatory evidence. The supracardiac dullness was wide and percussion would have doubtless shown it even wider had the lungs not been overinflated.

The x ray findings are also confirmatory.

In a case of mediastinal tumor at this age one naturally thinks first of thymoma, teratoma and Hodgkin's disease as the most likely possibilities. Later in life, substernal goiter, aneurysm or some other type of malignant tumor would be suspected but they are hardly to be considered here. Between the two first mentioned I do not believe it possible to differentiate without pathological investigation. Hodgkin's disease should show glands elsewhere or at least have had them in the past. Furthermore Hodgkin's is a more chronic disease and should show generalized constitutional symptoms. Acute leukemia with mediastinal glands would have an abnormal blood picture.

A PHYSICIAN: Could it be a tuberculous gland?

DR. ADAMS: It would have to be a tremendously large gland to give this picture.

A PHYSICIAN: If a case of thymoma is exposed to x ray does it not have a tendency to diminish the mass?

DR. ADAMS: Yes. But he did not receive treatment, only a diagnostic plate, and probably a portable one. Whether x ray treatment was not started immediately for fear of increasing the obstruction by reaction incident to therapeutic exposure I do not know, but that is a possible explanation.

A PHYSICIAN: I have seen one case of thymoma which acted almost exactly like this. Decrease in the size of the tumor was brought about by the x ray exposure in taking the diagnostic plate. The patient then received therapeutic doses and within a few days the mass had apparently completely disappeared. In a month's time, however, he began to have hemorrhages, and despite several transfusions died within two months.

CLINICAL DIAGNOSIS

Mediastinal tumor

DR. DENNETTE ADAMS' DIAGNOSES

Mediastinal tumor—teratoma or thymoma
' Bronchopneumonia terminal

ANATOMIC DIAGNOSES

Lymphoblastoma of the thymus (thymoma)
with pulmonary infiltration
Operative wound Tracheotomy
Hyperplasia of the spleen and mesenteric lymph nodes
Endocarditis, acute rheumatic, mitral
Pleuritis, chronic fibrous, bilateral
Chloasma

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY: What we found was a very large tumor in the anterior mediastinum which occupied the position of and completely replaced the thymus. It was obviously malignant in character and was infiltrating in all directions laterally into the lungs, and anteriorly and posteriorly through the mediastinal tissues. It has not penetrated the pericardium as these tumors sometimes do.

The diagnosis of course narrows down to what types of tumors occur in this region. In an old person you have to think of various other things that do not come under consideration here: a substernal goiter, cancer of the thyroid or metastases from a distant spot and so on. These are all practically ruled out by the age factor alone. Generalized lymphoma must of course be ruled out. A dermoid cyst or a teratoma of the anterior mediastinum are perfectly good possibilities in a child and there is no way to differentiate them from thymoma. It comes down to the question of one or another of these three tumors and of them thymoma is distinctly the commonest. What these so-called thymomas are, we do not really know. The thymus, as you will remember, microscopically is made up of a small amount of epithelium, ordinary squamous epithelium and of a large amount of what looks like lymphoid tissue. In older people, from fifty up, a tumor of the thymus stands a very good chance of being a squamous cell carcinoma. But in children it practically never is cancer and will usually look like a more or less typical lymphosarcoma, as in the case here. These tumors are very sensitive to radiation and Dr. Holmes felt in this particular case if they had gone a little farther with the tracheotomy—if they had pnt a tube down into the bronchi to establish an airway—and then had given him a small dose of x ray, it was perfectly possible that the patient could have been pulled through coming in even moribund as he did.

DR. ADAMS: Was there no cyst, hemorrhage or edema to account for the sudden increase in symptoms?

DR. MALLORY: These tumors of course lie just beneath the upper thoracic outlet which is a fairly small and very inelastic space. It is bounded by the first rib and clavicles on the side and front and by the vertebral column be-

hind A very slight shift of the tumor upward would wedge it into this outlet and make a tremendous difference in the amount of obstruction Variations in position might easily account for such a shift I suspect that when he was lying down he was much more obstructed than when he was upright

The majority of these tumors look like and probably are lymphomas Our diagnosis on this case was lymphosarcoma of the thymus However, it must be admitted that a case of lymphoma which fails to become more or less generalized is open to suspicion as to the correctness of the diagnosis Many of the cases starting in the thymus do not look or behave quite like lymphoma and there always has been a question whether all the round cells in the normal thymus are lymphocytes or not They look so much like them that so far the histologist has not been able to differentiate them with any certainty

A PHYSICIAN In this particular case if he had got exposure to x-ray you think he would have pulled through this attack?

DR MALLORY One can only guess at it If you could have got in one small dose of radiation without his suffocating he would have pulled through The whole question would have been whether you could have kept the airways

open long enough There is real danger of significant swelling of the tumor for a few hours after the x-ray treatment which might prove suddenly fatal

A PHYSICIAN What factor did the vagus have here? Was it entirely mechanical obstruction or was there some interference with the vagus?

DR MALLORY My impression was that it was entirely mechanical The phrenic lay closer to the tumor than the vagus but it obviously was not involved, since the diaphragm moved satisfactorily The vagus was far enough back so that it could hardly have been affected

A PHYSICIAN The question could be raised, inasmuch as you have this large mass here, whether the obstruction would develop so suddenly since it was mechanical

DR MALLORY I think it is again the question of a tumor mass filling the neck, and the difference of an eighth of an inch in diameter of the tumor would make the difference as to whether the neck was completely plugged or partially plugged

A PHYSICIAN Did he have the general appearance of a status lymphaticus individual?

DR MALLORY No, and the lymph nodes elsewhere were not enlarged

GRADUATE TEACHING

The problem of graduate teaching is becoming more and more acute. For many years several medical schools have attempted to meet the needs of those who have desired to improve their medical education. There are about twenty-eight medical schools in this country offering courses to graduates. The question is, "Are these schools to continue their programs indefinitely or will they endeavor to assume the real functions of medical education in its broadest sense, beginning at the point when the student receives his diploma?"

In the main the support of the so-called Post Graduate School is derived from the tuition of its students, which makes the institution a commercial one. The result of this is that the burden on the individual student seems large to him and the remuneration seems small to the teacher.

Graduate teaching today is carried on under the same conditions that prevailed in the undergraduate medical departments thirty-five years ago. No sane person wishes a return of those days. It would seem then, as a result of this unhealthy situation, that some sincere effort ought to be made to remove the graduate school from the arena of commercial medicine and put it in a more dignified place. Unfortunately, the public which needs the practitioner is unwilling to help the situation by endorsing graduate schools. Funds for research are given much more freely than for improvement of the product of the medical schools. The busy practitioner is unwilling to leave his practice for several seasons the fear of losing his practice while absent, the expense of maintaining his family and himself, the tuition, the leaving of his community without a physician and too frequently the fear of mixing with his city colleagues. He is afraid to ask questions and express his opinions and often there is lack of interest in self-improvement. All these facts are evident to those who have had contact with the problems of graduate teaching since less than four per cent of the practicing physicians of this country attend courses for graduates.

During the past few years Boards of Certification have been formed by several of the special societies which have laid down minimum requirements in order that a physician may be recognized as qualified to specialize. There is no regular organized scheme at present which will meet the needs of this situation.

A specialist, in addition to his clinical experience should have a fundamental knowledge of general pathology followed by training in pathology applying to his special field. The graduate school is the legitimate medium for organizing and managing this work. These schools therefore should abandon the insignificant place which they now occupy and strike out on a large, well formulated basis to care for the practitioner, the research fellow, the intern and the embryo specialist.

Such departments as are needed may be had from expansion of the undergraduate departments. This is probably advisable as the contact may stimulate the undergraduate to continue his studies as long as he is active. In order for graduate departments of medicine to assume the functions which properly belong to its life and welfare it is necessary to have the whole matter of graduate teaching thoroughly studied and investigated by some well-qualified person or persons who will report their findings and make recommendations. The time is ripe for such a procedure. The school, the physician and above all the patient will reap the benefit.

THE COMMONHEALTH

The Commonwealth, the quarterly journal of the Massachusetts Department of Public Health, lives up, in its current issue, to a high standard originally set and consistently maintained. For Number 2 of Volume 22 the editor has selected the general subject of personal hygiene, and as usual has presented an array of authorities who have written on many phases of this interesting and important subject.

Hygiene is today as much concerned with mental comfort, happiness and efficiency as it is with physical well-being, and it is fitting that the leading article, by Dr Ives Hendricks, should be on Clinical Psychology and Medicine, containing a brief résumé of the advances that have been made in our understanding and handling of the neuroses. Other contributions have to do with conservation of sight and proper lighting, the prevention of deafness, the care of the teeth, feet and skin, ventilation, air conditioning and heating, the preservation of foods, the preparation of meals, scientific facts about sleep, and recreation hobbies and dress.

A good work is being done in the preparation of these bulletins, and the layman who follows through with them will receive a sound education in those fundamentals of medicine, hygiene and public health which should be the property of all intelligent citizens. One wonders how many are aware of its existence and that it will be sent free to any citizen of the state who applies for it.

The list of contributors is necessarily great and it is not to be expected that all will write with an equal degree of interest and clarity. The facts presented, however, are all sound and should be valuable.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

DAVIS, CARL H. B.A., B.Sc., M.D. Rush Medical College 1909. F.A.C.S. Clinical Professor and Director of Department, Obstetrics and Gynecology, Marquette University School of Medicine. Obstetrician and Gynecologist, Columbia and Milwaukee County Hospitals. His subject is "Lesions of the Cervix Uteri—Diagnosis and Treatment." Page 699. Address 425 E Wisconsin Avenue, Milwaukee Wisconsin.

MORGAN, CHARLES E. A.B. M.A., M.D. Harvard University Medical School 1892. F.A.C.S. Visiting Surgeon, Holy Ghost Hospital for Incurables and Somerville Hospital, Senior Staff. His subject is "Changes in Maternal Mortality and Their Significance." Page 705. Address 24 Central Street, Somerville.

PEMBERTON, FRANK A. S.B., M.D. Harvard University Medical School 1909. F.A.C.S. Surgeon-in-Chief, Free Hospital for Women, Brookline. Clinical Professor of Gynecology, Harvard University Medical School. His subject is "Resection of the Presacral Nerve in Gynaecology." Page 710. Address 198 Commonwealth Avenue, Boston.

ZOLLINGER, ROBERT. B.S., M.D. Ohio State University College of Medicine 1927. F.A.C.S. Instructor in Surgery, Harvard University Medical School. Junior Associate in Surgery, Peter Bent Brigham Hospital. Address Peter Bent Brigham Hospital, Boston. Associated with him is

YOUNG, EDMUND. A.B., M.D. Harvard University Medical School 1934. Intern, Surgery, Lakeside Hospital, Cleveland, Ohio. Address Lakeside Hospital, Cleveland, Ohio. Their subject is "Observations on the Symptomatology of Cholelithiasis With Special Reference to Vomiting." Page 714.

DIAGNOSIS AND TREATMENT OF BENIGN ENDOMETRIOMATA OF THE OVARY

(Chocolate Cysts, Endometrial Cysts of the Ovary)

Perforating hemorrhagic or chocolate cysts of the ovaries are usually found in women between thirty and fifty years of age, are frequently bilateral with accompanying secondary implants to uterus, tubes, round ligaments, large and small intestine, bladder, and pelvic peritoneum, but unlike malignant ovarian tumors, rarely, if ever, found in the omentum.

*A series of short selected articles by members of the Section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

The preoperative diagnosis is difficult. In large endometrial cysts of the ovary there is often a history of sterility and severe acquired dysmenorrhea with acute attacks of pelvic pain occasionally rectal and vesical tenesmus. The condition is often associated with fibroids and other pelvic disorders making the diagnosis uncertain. With such a history and a pelvic examination that reveals a conglomerate tumor, a fixed uterus with inflammatory like masses in the region of the adnexa and a nodular infiltration or scar like formation in the endometrium the indications point strongly to hemorrhagic ovarian cysts.

At operation one or both ovaries will be found to be enlarged and cysts containing a typical dark, syrupy material, with dense adhesions involving adjacent structures making removal extremely difficult.

Treatment. The differential diagnosis presenting a difficult problem especially excluding pelvic inflammation and knowing there are adhesions and fixation of the organs, relief is best effected by mechanical procedures. Surgical intervention is indicated when the patient is considered a reasonably good surgical risk rather than treating with x-ray or radium. It is recognized that the growth of the implants are dependent on the functional activities of the ovaries therefore all ovarian tissue should be removed. Secondary implants should be removed when easily possible. When implants are extensive and difficult to remove, such as those found on the intestine and bladder an attempt at removal should not be undertaken as these lesions in a majority of cases will atrophy and be followed by relief of resulting symptoms when the ovarian tissue has been completely removed. If there is activity after operation or the patient is an extremely poor surgical risk, irradiation may be employed in an attempt to inactivate the ovarian function.

THE 1936 ANNUAL MEETING

At the Council Meeting October 3 the Committee on Arrangements reported that the next Annual Meeting of the Massachusetts Medical Society will be held on June 8, 9 and 10, 1936 at the Hotel Kimball, Springfield.

PUBLIC RELATIONS COMMITTEE

COMPULSORY SICKNESS INSURANCE NOT THE ANSWER

Compulsory sickness insurance is a system of insurance, administered either by the Government or by some type of commercial insurance organization to which certain designated groups in a community are compelled by law or as a condition of employment to subscribe. These designated groups are determined on the basis of certain income levels. These income levels have been placed by various pro-

ponents at different amounts. The general idea however being that it shall not exceed an amount necessary to supply the essential comforts of life.

In the feudal state the overlord was charged with the care of his dependents. In the trades, the guilds assumed the responsibility but with the great and unrestricted and rapid growth of industrialism with its machines and impersonalities, with its alternating surplus and shortage with its failure oftentimes to share profits equitably with the worker all this was changed and there developed a type in our population which was not able to care for even its basic needs and for which nobody seemed responsible.

This failure on the part of our industrial system to provide sufficient wealth for every willing worker to care comfortably and completely for himself and his family in their essential needs brought into being the social concept, which is in effect, that because the public tolerated an abuse it was bound to do what it could to relieve the abused.

While some attempts have been made to correct the abuses of industrialism we had rather come to think of them as inevitable as something inherent in the system as something that could not be changed without wrecking the whole. We rather think this problem has grown to such vast proportions before we even recognized we had a problem that its magnitude appeared too formidable for us and we turned to the easier way of making it up to industry's abuses by means of charitable and social agencies in the presence of a malignant disease that might have been cured by early operation we threw away the scalpel and administered a shot of dope.

Doctors know of these charitable and social agencies as no other group does. They have been caring for industry's oppressed in their charitable clinics within and without hospitals for many years. They have seen these clinics grow to enormous magnitude, representing services which if paid for would amount to more than \$100,000,000 each year. Social service was the doctor's handmaiden. The greatest impetus to its growth comes from doctors.

Is it any wonder then that doctors think that they are entitled to have something to say about the trends which these agencies are assuming? Nobody in the profession questions that grave abuses have been allowed to creep into free clinics. A friend of the writer giving his services to a large metropolitan hospital can find no place to park his car because the outpatients have pre-empted all the parking space. Nobody who watches the trends of the last few years has any doubt but that the professional sociologist seeks the domination of medical practice.

This original concept of compulsory sickness insurance was designed to so spread the cost of sickness for those of small means over such large numbers as to make it unburdensome for each. Nobody questions the wisdom of this as a statement of an ideal. It would be most difficult to find any doctor who was not in entire sympathy with such a proposal. Thinking men however are wont to distinguish between a stated ideal and the application of that ideal to everyday life.

Compulsory sickness insurance has been offered as the instrument by which that ideal is to be realized. Let us see how well this system has maintained that ideal in the several countries in which it is already in operation. In every country in which has been inaugurated a system of compulsory sickness insurance the original concept of providing first class medical care for those economically unable to provide it for themselves has been lost sight of and there has taken place either an extension of or a tendency to extend the benefits to increasing num-

bers of the population irrespective of their abilities to provide for themselves. The figures to support this statement are available to anyone who cares to investigate. We find that this system of sickness insurance has so grown in the numbers covered that today it covers 63 per cent of the German, 76 per cent of the Austrian, 75 per cent of the Belgian, 65 per cent of the Danish, 31 per cent of the English, 61 per cent of the Swedish and 75 per cent of the Czechoslovakian populations. During the present year, 1935, there has been much agitation to very materially increase England's figures.

It is rather interesting to inquire as to why this ideal has not worked according to its original conception. We think the answer is to be found in the character of the institution that first offered it and has since controlled it, an institution that appears to be the same the world over, the institution of politics. Every one knows that there are very few ideals which politics touches that it does not ultimately blast.

The voice of the people has never been in demand for compulsory sickness insurance. Because labor has never been very much interested in the social concept, because it has never been interested in trading a steady job at a living wage for a bowl of soup, because it has never been interested in substituting social responsibility for personal responsibility, it has never been interested in compulsory sickness insurance. Furthermore, labor should never be deceived by the promises which such a system offers. Labor should know that as the ultimate consumer it pays, not part of the bill, but the whole bill. Labor should know that the employees share is not a gift but something either taken out of wages or tacked on to the cost of the article produced which in turn labor must buy. Labor should know that it pays for the host of administrators, for the ornate and costly administrative buildings and equipment. It pays a bill far in excess of that which it paid when it received its medical care from private sources. (See "Handbook of Sickness Insurance and State Medicine and the Cost of Medical Care" Page 20.)

In 1881 Bismarck was in the process of realizing his crowning political effort—the unification of a strong German Empire. There was however a body of German citizens who, feeling oppressed by the industrialism of the time, were more interested in bettering their economic position than in Bismarck's dream. These Social Democrats, as they were called, had grown to such numerical strength by 1883 that they seriously threatened the policies of the crown. To attract votes from this group, to show the benevolence of the crown Bismarck had passed the first formal compulsory sickness insurance act. Gottlieb Pick, a German writing in the "Sozialversicherung und Aerzte" 1931, page 56, has in this connection the following to say: "Bismarck's original plan arose out of a combination of the capitalistic with the feudal and fraternal mental attitude. Governmental care was to make clear to the eyes of the worker how much the state cared for them and thereby make them contented and loyal."

This German system has now been in operation more than fifty years. It has been and is changing with great rapidity due to the constant dissatisfaction with the details of the law. This constant alteration has brought about a most complex situation, so that today there are 3,000 sections of the German laws on compulsory sickness insurance. What a paradise for the bureaucrats!

The demoralizing effect which this system has had on the German citizen has been well put by a German physician, M. Kirschner, who writing in "Zur Praxis der Begulachtung" has the following to say: "The insured also believe since they have

long contributed to the cost of insurance, that after a certain time they have the right to receive some money from it. It is easy to implant the idea in the consciousness of a simple man. 'Now that I have paid so long, I will at last get something out of my insurance.' In this way the ominous will to be sick is artificially created and social institutions are many times practically compelled to put a premium on sickness, laziness, exaggeration and deceit, so that the individual who is in a manner the innocent victim of these compulsory institutions, cannot make any special individual objection. Since legal compulsion has today brought the majority of the population within the scope of social insurance, a constantly increasing proportion of the workers is being brought into a condition of subjection to these institutions."

Present day Germany has been compared to a great lazaret or home for crippled where each individual is trying to get as much as possible out of the gigantic pension cup, which is kept filled by ever increasing contributions. Every seventh German is today a "social pensioner." In this same connection let us listen to what Gustav Hartz, a German labor leader and economist, also has to say, writing in the *New York State Journal of Medicine*, March, 1935: "The sickness insurance provides the workman with medical attendance free of charge, with medicine and other necessities and with an allowance. Any one will at first sight consider this a great blessing for the workman as well as for national health. The reality, however, is very different. Dread of illness obsesses most people and this has been pressed into a system 'illness made easy' by which the will to be well has been strangled. The doctor is consulted a dozen times where once would be sufficient—the insurance pays. The prescribing of medicine, bandages, etc., is desired. When they are obtained they lie about until they are no longer fit to be used and must be thrown away—the insurance pays. Besides it is nice to get something in return for the premiums paid year in and year out. Excessive over doctoring is the result. Pretenders and hypochondriacs are bred and the use of medicine becomes excessive. A few years ago it was estimated that four times as much money was used for doctors' fees and medicines for 35,000,000 of people in insurance as for 30,000,000 of uninsured. At first sight it seems improbable and paradoxical that a desire to obtain sick money that scarcely amounts to half the sum of wages should arise. It appears impossible that some one should, unless compelled by illness, forfeit his wages to get an allowance of half the amount. In millions of cases, for example, when wages are being decreased, when work is scarce and work hours shortened in consequence, when there are fewer shifts, many holidays, work restrictions in certain seasons, outdoor work in frosty weather, 50 per cent of the wages are welcome. One objects to the work he is given, another does not feel like working, a third's time is taken up by some family matter for which he would have to take leave of absence and forfeit his pay. In such cases sickness insurance comes in handy. Doctors are induced to prescribe medicine and instead of medicine toilet soap and scent are handed out by the pharmacies." How is this possible, you ask? Hartz answers that by saying that "under compulsory sickness insurance medical science has become a cheap article and doctors have given up conscientious treatment." This is not a very beautiful picture which Hartz paints. It strips human nature pretty bare. But it is in accord with a fairly generally accepted view.

Gottlieb Pick writing in *Sozialversicherung und Aerzte* 1932, page 40, tells us of the enormous administrative bureaucracy which has been built up in Germany by its compulsory sickness insurance sys-

tem. It tells us that the numbers of the Krankan hassen, the administrative side of the system has grown to be practically the same as the number of physicians engaged in giving medical service.

None of these systems are self-supporting. They all depend on governmental subsidy with the inevitable increase in taxation. No reserves are built up by such systems of insurance. Birth, old age and death permit of fairly accurate determinations but there are so many moral elements which enter into this business of compulsory sickness insurance as to preclude the possibility of sound actuarial guidance. It is a hand-to-mouth existence which such systems must lead. In times of unemployment their costs must increase and the awards must decrease. They cannot pay out what they do not take in. This breeds trouble with the worker who believes because he has for years paid into such insurance he is entitled to a definite fixed award in his time of need. The only other alternative is to dip deeper and deeper into the public treasury. It is held by many insurance experts that it is not insurance at all because it does not take into consideration the more or less fixed elements on which insurance is founded.

In 1911 David Lloyd George was having some trouble in England in maintaining his control of the British Government. There was an election in the offing. He was being pressed on the one hand by the Conservative and on the other by the Labor Party and it looked as if the pressure exerted by these two forces might squeeze him and his Liberal Party out of the political picture. He felt that this would be a catastrophe for England and must not be allowed to happen and so his working hours were entirely taken up in formulating plans and furthering schemes for saving England and David Lloyd George. Then one night he sat up late reading German history as a relaxation from the arduous labors of the day. He learned of a German statesman who several years before flooding himself in much the same position hit upon the expedient of compulsory sickness insurance as a means of demonstrating his interest in and sympathy for the laboring man. He closed the book and went to bed. The German history had solved his problem and thus was born England's compulsory sickness insurance idea.

This English plan demands our closest scrutiny. Because it, more than any other, is being talked of as the model for the proposed American system.

It might be well at this point and for the moment to address ourselves to those few doctors who while not necessarily favoring do assume a fatalistic attitude toward this matter of compulsory sickness insurance. It is coming anyway. No matter what we do about it. So why bother to try to do any thing. The Massachusetts Medical Society decries this attitude and the Public Relations Committee wishes to call to the attention of those this fact, that whatever merit there may be in the English system was had only because of the vigorous stand which the British Medical Association assumed in opposition to the iniquitous plan as originally proposed by David Lloyd George.

Under the English system all workers with a few exceptions who earn 250 pounds or less each year are compelled to subscribe. The worker has removed from his wages 9 pence each week. The employer adds 9 pence more and in addition the Government contributes an amount which when taken with that obtained from the other two sources will keep the system going. This latter amount during the last year was 18 per cent of the total cost. This worker alone is insured. His dependents are not. For his or her contribution the worker receives medical services, treatment and all those medicines and other

therapeutic aids which the doctor deems necessary. When his or her illness is of such character as to unfit either for work and ho or she is so certified by the doctor he or she receives certain cash benefits. When a worker's wife has a baby he receives a pound and when the wife herself is also a worker two pounds are added to the family budget.

The act provides for the services of the general practitioner only. It does not provide for hospitalization or the services of specialists. Any doctor licensed to practice medicine in England is eligible to do this kind of work. It is only necessary for him to indicate his desire to the Ministry of Health and his name will be placed on the panel which hangs in the local post office. The worker makes his selection from this panel. Once the work or has selected his doctor and has consulted him he must remain the patient of that doctor for one year unless the doctor is willing to give him up. In the case of disputes on this and other matters there is provided a tribunal which will hear the grievances and render a decision. In addition to treating the patient, in certain rural communities, where there are no pharmacies the doctor must dispense medicines and for this latter he receives special remuneration. He must record his calls on special cards supplied by the insurance committee.

When the insured's incapacity to work is doubted the doctor must supply the regional officer with appropriate information in the form of a written report. He must at all times be ready to answer charges of negligence brought against him by insured patients.

The doctor's remuneration is about \$2.25 per insured person per year. The average ratio of insured to insurance doctors at this time is 1000 to 1. If this work were evenly divided among these doctors, each doctor's top each year would be \$2,250.00. Forty nine per cent of the English doctors are engaged in this type of work. These doctors may also engage in private practice.

It is estimated that the expense of a panel practice is \$1100.00 per year. The figures released by the British Ministry of Health a few months ago give an average gross annual income to the panel doctor of \$1960.00—or a net annual income from this source of \$860.00. It being axiomatic that one receives according as one pays at least it suggests itself that such service might possibly leave much to be desired. The fact is it is cheap service and at best second-class service. This is true not only in England and Germany but in all countries harboring systems of compulsory sickness insurance and nobody seriously questions this fact.

The proponents of the English system point to what they are pleased to call its low administrative costs and they point with pride to the English Civil Service system as one of the main reasons for these low costs. Nobody questions the excellence of the English Civil Service. It is one of the finest in the world. The Royal Commission on National Health Insurance is however not particularly impressed that these costs are low but thinks quite the contrary. Let us put it in their own words: "We should have expected that very large societies having at their disposal for purposes of administration of National Health Insurance, they call it Health Insurance in England all the machinery of a huge business undertaking, would have been able to carry on their administration at an appreciably lower cost per head of membership. We are surprised to find that this is not the case. For the actual administrative costs however let us have a look at the figures supplied by the British Ministry of Health for the year 1934. During that year the cost was \$23,820,000. For every dollar spent on the insured fifteen cents was spent

on administration Quite a tidy sum to come out of the workers for the administration alone of a second rate article Imagine if you can what these costs would be in this country where we have to muddle along without the excellence of the English Civil Service and where we enjoy an administration which tosses billions around as if they were toy balloons

The administration of the English system is quite complicated At its top is the Ministry of Health Certain approved Societies and Commercial Insurance Companies complete in a general way the administrative setup Theoretically the commercial companies do their work without profit, actually, costs are so manipulated that a very tidy profit is realized Those of us who have had any contractual contacts are familiar with cost plus plans We know how these costs may be and are juggled, and we furthermore know that from these same costs come plenty of gravy

Does the English worker like the system? I think in a general way he does To quote Sir Frederick Treves "The English working class has a craving for bottles of medicine which is second to the craving for strong drink" This system permits him to indulge this fancy to his heart's content without reckoning on its purchase price He enjoys running to the doctor with his trivial complaints distracting the doctor's time and attention from those who really need them What a paradise for the neurotic! Nor, we are told, is this controllable Refusal to supply these bottles of medicine means lost patients, and patients' families and friends and lost patients mean lost income, and here we have at the very beginning an invitation to moral let down of which we will have more to say later

Is the English worker's health better since the establishment of the insurance system? There is no evidence that it is and if we are to accept the figures of the British Ministry of Health for a six year period, 1921 to 1927, we are forced to one of two conclusions, either his health is very much worse or he has developed malingering to a fine art These figures tell us that the morbidity rates as indicated by benefit claims had increased during that period 41 per cent for men, 60 per cent for unmarried women and 106 per cent for married women

Has the system lessened the time lost to industry by reason of the worker's illness? There is no evidence that it has On the contrary there is evidence that it has not Previous to the existence of compulsory health insurance in England the English and American workman lost about the same number of days each year because of illness Today the English workman loses ten days each year and the American 65 days for this reason

How has compulsory health insurance affected mortality rates in England? There is no evidence that it has affected them favorably and in this connection it at least is interesting to note that during a period of twenty years ending 1933 the English mortality rates dropped less than 10 per cent, while during this same period these rates dropped 21 per cent in the United States

In England under this system the interest has been focused on the care of those actually ill and the emphasis has been largely away from preventive medicine as we know it in this country

What about the amounts expended for poor relief? Has it been lessened in England under compulsory health insurance? It was expected that it would There is no evidence that it has and while the insurance is for the worker and the care of the indigent does not come within the scope of the insurance act, it was expected that the poor law agencies would be relieved of the care of that great

horde of workers whose wages were so low that they could not pay for their own medical care It has, however, not worked out that way Dr R G Leland writing in the *Bulletin of the American Medical Association*, October, 1934, says that "the expenditures for this purpose have increased continuously ever since insurance went into force, and with in the last two years the most extensive measures in this direction ever proposed in England have been put into operation Some of these are much the same as those proposed by the Royal Poor Law Commission in 1909 and then rejected in favor of insurance" The vast unemployment of the times may have something to do with this and undoubtedly has This condition however does not constitute by any means the whole explanation We know that during the first two years of insurance, Governmental and privately supported clinics were very materially decreased in attendance but since that time there has been a steady and rapid trek back to these charitable clinics so that today more people are being treated by these agencies than ever before and their rolls by no means are made up entirely of the indigent and unemployed but contain the names of vast numbers of workers who are already covered by insurance

Webster defines morals as the science or doctrine of right conduct While conduct may be related to point of view, among all peoples there are certain fundamentals upon which all are in accord Honesty in thought and act is one of these The invitation to dishonest practices upon the part of the doctor and worker is everywhere recognized as one of the great evils of compulsory sickness insurance not only in England but in every country in which such a system is in operation When the insured resents the doctor's lack of cooperation in making it possible for him to draw an extra week's benefit, when work is slack or when he thinks he needs a vacation, he is apt on the first possible occasion to change his doctor Pretty soon the word is passed around that Doctor So and So is very strict and pretty soon Doctor So and So finds he has no patients Compulsory sickness insurance places the doctor on the spot.

It has been said that the English doctor likes compulsory sickness insurance This may be true It is easy to understand why it may be true Before the advent of insurance in England a large amount of medical service was dispensed through the medium of clubs So terrible was the competition that many doctors employed solicitors or runners who sought to sign up patients for them at two pennies a week These were intolerable conditions from any standpoint Any system which changed this must be an improvement, as anything worse is not conceivable So when we are urged to accept compulsory sickness insurance because our English brother may like it let us remember these facts and the speciousness of such an argument will be apparent

Doctors who have opposed compulsory sickness insurance for this country have been accused in the lay press of being reactionary and devoid of sympathy and understanding of the needs of many of their fellow citizens This criticism, we believe, is not vicious, but is due to a failure on the part of editors to understand the doctor's point of view For this the doctor himself is very largely to blame We have built a high wall around our motives and aspirations We know their purity We know that the well-being of humanity as it touches the doctor, occupies first place in his heart and mind Who else knows it? When an editor looking at an abstract ideal and finding it good criticizes the doctor who opposes the application of the ideal, too much fault should not be found with him, because the doctor is either

too inarticulate or too proud to explain the reason for his opposition

In this campaign of public education let us tell the editor and the public at large that we even more than they are eager that *first class medical care* shall be the heritage of every resident of our country and that they may know that this is not high sounding clap-trap let us point to the millions in service which the doctors of this country pass on yearly to their underprivileged fellow citizens. Let us tell those sweet chair well-fed and well-paid sociological romancers who have never treated a patient, who busy themselves with their graphs, diagrams and mathematics that we even more than they are concerned with the health of our fellow man. Let us remind our people that mass production methods will yield poor dividends in health. Let us remind our people of the necessarily intimate personal relationship of patient and doctor with the direct responsibility which one shares with the other. Let us ask him if he desires the political messing around in that relationship. If compulsory sickness insurance has so completely failed to realize its objective in providing *first class medical care* in countries like Germany and England with their homogeneous populations what can be expected of it in a country like ours with its extremely heterogeneous make-up? How could our Federal Government formulate a compulsory sickness insurance law that would be workable in each of our forty-eight states? The problems of no two are alike. What might be good medicine in the Carolinas might very well be poison for Massachusetts. The citizens of the United States have not been cast in a common mold. Their private lives are built around the traditions of their origin and it may be a hundred years before and maybe never will our citizenry think as a unit in matters that touch closely their homes and families.

Maybe we do need some change in Massachusetts in the way in which medical care is made available. Who knows? Certainly not the fellow who takes a hop skip and a run view of the whole country. Certainly not the Committee on the Costs of Medical Care from whose majority report comes a great deal of the urge for compulsory sickness insurance. This committee in its survey did not touch Massachusetts at all. The fact is nobody knows. The Massachusetts Medical Society intends to know and is in the process of knowing through the activities of the committee on the adequacy of medical care, a sub-committee of the public relations committee.

The Massachusetts Medical Society is committed to an honest and intelligent attempt to find the truth and furthermore pledged to sponsor remedies where needed. Can any editor or citizen question the logic of such a procedure? Tell them of our plans. We of the committee are sure that they will listen eagerly and respectfully and much good will have been done.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning October 13

Barnstable

Sunday October 13 at 4 00 P.M., at the Cape Cod Hospital Hyannis Subject Cancer of Breast and Uterus Sarcomas of Bone Lymphoma and Leukemia. Their Early Diagnosis Discussion of Life History of Cancer and Grades of Malignancy Instructors C O Simmons, A O Hampton and C L Parsons J I B. Vall M.D., Chairman

Bristol South (Fall River Section)

Monday October 14 at 4 00 P.M., at the Stevens Clinic of the Union Hospital Prospect Street, Fall River Subject Dermatology Ten Common Skin Diseases — Diagnosis and Treatment. (1) Impetigo Contagiosa (2) Scabies (3) Acne Vulgaris (4) Psoriasis and Seborrheic Dermatitis (5) Epidermophytosis (6) Herpes Simplex and Zoster (7) Eczema (8) Erythema Multiforme (9) Verruca Vulgaris (10) Dermatitis Medica mentosa and Dermatitis Venenata Instructors C G Lane Eugene A. McCarthy M.D., Sub-Chairman.

Essex North

Friday October 18 at 4 00 P.M. at the Hotel Bartlett, 95 Main Street, Haverhill. Subject Cancer of Breast and Uterus Sarcomas of Bone Lymphoma and Leukemia Their Early Diagnosis Discussion of Life History of Cancer and Grades of Malignancy Instructors G A. Leland and Shields Wmron Francis W. Anthony M.D., Chairman

Essex South

Tuesday October 15 at 4 00 P.M., in the Nurses Home of the Salem Hospital Salem. Subject Arthritis (a) Medical Care of Patient in the Home (b) Orthopedic Treatment in Hospital and Aids in Home Treatment. Instructors J S Barr and H A Nissen Walter G. Phippen M.D., Chairman

Hampden

Thursday October 17 at 4 00 P.M., at the Academy of Medicine Professional Building 20 Maple Street Springfield and at 8 00 P.M. at the Holyoke City Hospital Holyoke Subject Diseases of the Liver Surgical Problems in Diagnosis of Acute Disease of Gall Bladder and Liver Instructors E. S. Emery and H M. Chute George L. Schadt M.D., and George D. Henderson, M.D., Chairmen.

Hampshire

Wednesday October 16 at 4 15 P.M., in the Nurses Home of the Cooley Dickinson Hospital Northampton Subject Arthritis. (a) Medical Care of Patient in the Home (b) Orthopedic Treatment in Hospital and Aids in Home Treatment. Instructors A H. Brewster and A. A. Hornor Robert B. Brigham M.D. Chairman

Middlesex East

Wednesday October 16 at 4 00 P.M., at the Melrose Hospital Melrose Subject Arthritis (a) Medical Care of Patient in the Home (b) Orthopedic Treatment in Hospital and Aids in Home Treatment Instructors R. B. Osgood and F. C. Hall Joseph H. Fay M.D., Chairman.

Middlesex South

Tuesday, October 15, at 4 15 P M, at the Middlesex County Sanatorium, Waltham Subject Lung Diseases (a) Differential Diagnosis and Treatment of Lobar Pneumonia (b) The Surgical Problems of Empyema. Instructors H F Newton and D S King Edmund H Robbins, M D, Chairman

Norfolk South

Monday, October 14, at 8 30 P M, at the Quincy City Hospital, Quincy Subject Immunology Latest Developments in Immunization Smallpox, Typhoid, Measles, Scarlet Fever, Diphtheria, Whooping Cough and Infantile Paralysis Instructor G W Anderson David L Belding, M.D, Chairman

Plymouth

Tuesday, October 15, at 4 00 P M., at the Brockton Hospital, Brockton. Subject Dermatology Ten Common Skin Diseases—Diagnosis and Treatment. (1) Impetigo Contagiosa, (2) Scabies, (3) Acne Vulgaris, (4) Psoriasis and Seborrheic Dermatitis, (5) Epidermophytosis, (6) Herpes Simplex and Zoster, (7) Eczema, (8) Erythema Multiforme, (9) Verruca Vulgaris, (10) Dermatitis Medicamentosa and Dermatitis Venenata. Instructor J H Swartz Walter H Pulsifer, M D, Chairman.

Worcester North

Friday, October 18, at 4 30 P M, at the Burbank Hospital, Fitchburg Subject Immunology Latest Developments in Immunization. Smallpox, Typhoid, Measles, Scarlet Fever, Diphtheria, Whooping Cough and Infantile Paralysis Instructor E S A. Robinson Edward A. Adams, M D, Chairman

MISCELLANY

HARVARD UNIVERSITY NEWS ITEMS

Four physicians from the Harvard Medical School and two physicians from the staff of the Massachusetts General Hospital have joined the Harvard Department of Hygiene as assistants to Dr Arlie V Bock, Henry K Oliver Professor of Hygiene and director of the Medical Service at Harvard University The appointments run for one year from September 1, 1935

Of the new appointees, five will carry the title of Assistant Medical Adviser They are Dr Clark Wright Heath, Instructor in Medicine, Harvard Medical School, Dr Greene Fitzhugh, formerly Assistant in Medicine, Harvard Medical School, Dr Jackson Mash Thomas, Assistant in Psychiatry, Harvard Medical School, Dr Kenneth James Tillotson, Instructor in Psychiatry, Harvard Medical School, Dr Vernon Phillips Williams, Assistant Psychiatrist, Massachusetts General Hospital, S B

Harvard '24, M D Harvard '28, and Dr John William Cass, Jr, Assistant in Medicine, Massachusetts General Hospital, Ph D Boston College '25, M D Yale '29

Dr Seth Marshall Fitchet, Assistant in Orthopedic Surgery, Harvard Medical School, will be Assistant Surgical Adviser

These appointments are in addition to those of five Assistant Medical Advisers and five Assistant Surgical Advisers in the Hygiene Department announced last spring

Awards of forty-one scholarships totaling \$10,095 to the following students in the Harvard Medical School this year were recently announced.

William McD Hammon, 4M, of Pittsburgh, Pa., Lewis Dexter, 4M, Beirut, Syria, James F Whitten, 4M, of Amesbury, Mass, Ferdinand F McAllister, 2M, Brooklyn, N Y, Charles A Robinson, 2M, Bronxville, N Y, William H Sweet, 4M, Centralia, Wash, Lewis Thomas, 3M, Flushing, N Y, James B Blodgett, 4M, Detroit, Mich, Arthur L Abrams, 2M, Roxbury, Mass, Walter H Pritchard, 4M, Binghamton, N Y

Newell R. Kelley, 3M, of Hartford, Conn, Lewis G Shepler, 3M, Mystic, Conn, Orvar Swenson, 3M, Independence, Mo, Seth H Read, 3M, Belfast, Me, Robert D Woolsey, 3M, Maquon, Ill, Henry H. Work, Jr, 3M, Buffalo, N Y, Marshall deG Ruffin, 4M, Roanoke, Va, Henry B Garrigues, 3M, Conshohocken, Pa, Murray S Howland, Jr, 3M, Binghamton, N Y, Richard B Pippitt, 3M, Port Jervis N Y, Vincent P Gruzdis, 2M, Worcester, Mass

Frank J Lepreau, Jr, 2M, of Hastings-on Hudson, N Y, Frederic D Lake, 2M, Perth Amboy, N J, Joseph Foster Ross, 4M, Covina, Calif, Robert B Lawson, 4M, Foxborough, Mass, Calvin T Klopp, 2M, Reading, Pa, George T Howard, Jr, 3M, Lexington, Ky, Ralph E Durkee, Jr, 4M, West Hartford, Conn, Espey F Cannon, 4M, Salt Lake City, Utah, William H Mathews, 4M, Whitesboro, N Y, David McL Greeley, 3M, Madison, Wis

Charles W Hayden, 2M, Kansas City, Mo, Elliott S Hurwitt, 3M, Brookline, Mass, Palmer Congdon, 4M, Waban, Mass, Samuel T Clarke, 4M, Honolulu, T H, Francis McC Ingersoll, 2M, Tecumseh, Neb, Donald E Nitchman, 3M, Schenectady, N Y, Robert P Tucker, 2M, Charleston, S C, John Maier, 2M, Royersford, Pa, Robert S Thomson, 2M, Milton, Mass, and Charles E MacMahon, 4M, Seattle, Washington

RECENT DEATHS

FRIEDMAN—NATHAN M. FRIEDMAN M.D., of 1067 Bine Hill Avenue Dorchester Massachusetts, died at his home October 3 1935

He was born in 1884 and after graduating from a German Medical College subsequently graduated from the Tufts College Medical School in 1909

He was a fellow of the Massachusetts Medical Society and the American Medical Association.

During the World War he served as an examiner for the Medical Board. He was secretary of the Jewish Hospital for Chronic Diseases Roxbury and a Mason. Dr. Friedman is survived by his widow Mrs. Isabel (Frank) Friedman and two sons Elliot Friedman and Theodore Friedman

KLEIN—ALVIN WALTER KLEIN M.D., of Stockbridge, Massachusetts, died September 27 1935

He was born in Owenton Kentucky February 2, 1868, educated in the public schools of Cincinnati and received his medical degree from the Cincinnati College of Medicine and Surgery in 1889. He practiced for a time in Cincinnati. After serving in the New York State Hospital Service and the U. S. Army

Medical Corps he became associated with the Austen Fox Riggs Foundation serving both as physician and trustee. He was a fellow of the Massachusetts Medical Society and the American Medical Association. The only surviving relatives are nieces and nephews living in Sherbrooke, Canada and New Rochelle, New York.

HICKSON—WILLIAM JAMES HICKSON M.D., of Pittsburgh Pennsylvania, died at his summer home in Olmsted Massachusetts October 4 1935

He was a well known psychologist with especial interest in criminology

He had had a varied experience in criminal courts in Chicago and elsewhere

Dr. Hickson was a graduate of Duquesne University and Pittsburgh University and received his medical degree from the University of Pennsylvania Medical School in 1900

He was a member of the Illinois Medical Society the American Medical Association the Philadelphia Psychiatric and other scientific orders.

He is survived by his widow Mrs. Marie Katherine Kittner Hickson.

WHEELER—LEONARD WHEELER M.D., of 12 Chestnut Street Worcester Mass., died at his home October 2 1935

Dr. Wheeler was born in Lincoln, Massachusetts August 31, 1845 the son of Abel and Charlotte (Bemis) Wheeler. His early education was acquired in the public schools of Lincoln. In 1862 he graduated from Phillips Exeter and in 1866 from Harvard College. He received his M.D. degree from Harvard in 1870 after serving an internship at the Massachusetts General Hospital. He pursued post graduate studies in Vienna and Breslau before settling in Worcester where he became prominent in hospital and consultation practice and was honored by the District and State Societies.

Dr. Wheeler is survived by his widow Mrs. Elizabeth B. C. Wheeler three sons Dr. Bancroft C. Wheeler Mr. Leonard Wheeler Nathaniel Wheeler and a daughter Miss Eunice Wheeler

NOTICES

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 P.M. on Thursday October 17 in the amphitheater of the Peter Bent Brigham Hospital Dr. Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physio in the Harvard Medical School will give a medical clinic. To it are cordially invited practitioners and medical students. These clinics will be repeated on Thursdays October 17 and May

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 to 12 staff rounds will be conducted by Dr. Christian

NEW YORK ACADEMY OF MEDICINE LECTURES

The New York Academy of Medicine has arranged for a series of lectures addressed to the lay public.

The opening lecture October 4, by Dr Walter B Cannon of the Harvard Medical School was under the title of the "Wisdom of the Body" Seven lectures by outstanding authorities are to follow

The subjects will deal with the "art and romance of medicine," the "methods of medicine," how "medicine achieved its goals", and "how it is striving for those unattained"

Disease and disease prevention will not be discussed

BOSTON UNIVERSITY SCHOOL OF MEDICINE
SURGICAL CLINIC AT THE BOSTON CITY HOSPITAL

Friday, October 11, 12—1, Cheever Amphitheatre Dr William R Morrison, Associate Professor of Surgery, will present

- 1 Posterior gastro-enterostomy for obstructing duodenal ulcer
- 2 Two-stage Lahey operation for cancer of rectum
- 3 Indirect inguinal hernia.

Physicians and medical students are invited

MASSACHUSETTS MEMORIAL HOSPITALS

The Surgical Section will resume its monthly meetings on October 11, 1935 The meeting will be held in the Ladies Aid Room (former nurses dining room), Falbot Memorial, 32 East Concord Street, Boston, at 12 noon on the above date

Dr Frank E Barton will speak of his "Observations in Hospitals in Europe" and papers will be presented by Dr Samuel L Marnoy, Dr Leo J Lynch and Dr Phillips L Boyd

MILO C GREEN, *Secretary*

DR. WILLIAM D McFEE ELECTED SECRETARY
OF THE NEW ENGLAND PHYSICAL THERAPY SOCIETY

At a Council Meeting of the New England Physical Therapy Society held at the Hotel Victoria on September 25, Dr William D McFee of Boston and Haverhill was elected Secretary of the organization to succeed the late Dr Arthur H Ring of Arlington who had been the Secretary since 1930

REPORT AND NOTICES
OF MEETINGSTHE ANNUAL MEETING OF THE NEW
ENGLAND SURGICAL SOCIETY

For the second time in its history the New England Surgical Society was invited to hold its annual meeting in Manchester, New Hampshire, this year September 27 and 28 were selected and the Local Committee, Dr David W Parker, Dr George C Wilkins and Dr Ezra A. Jones, arranged and conducted a most admirable program On Friday morning the local men operated at the Elliott Hospital and at ten o'clock the following dry clinic was conducted

Dr John P Bowler, Compound Fractures
Dr Emery M Fitch, Carcinoma of Penis
Dr George C Wilkins, Cancer of Mouth
Dr Thomas W Luce, Pick's Disease
Dr Ezra A. Jones, Leg Lengthening (Infantile),
Fracture Neck of Femur, Sedimentation Test (Résumé)

Dr David W Parker, Prolapse of Rectum, Obstruction at Ligament of Treitz (Torsion), Meckel's

Diverticulum Evisceration of the Bowels at the Umbilicus Ten Hours After Birth.

Dr James W Jameeson Meckels Diverticulum Dermoid Cyets.

Dr James B Woodman Fractured Patella.

A delicious buffet lunch was served at the hospital and considerable time was given the men to sit around and talk to their companions a very valuable part of the annual meeting of this Society

At two o'clock in the Ballroom of the Carpenter Hotel the following papers were read

Malignancy of the Breast, Dr H Gildersleeve Jarvis

Results in Mammary Carcinoma at the Elliott Hospital Dr George C Wilkins Dr George F Dwinell—by invitation

Secondary Carcinoma of the Large Bowel Dr Edward L Young Jr

One Hundred Untreated Cancers of the Rectum Dr Ernest M. Daland

Stones in the Common and Hepatic Bile Duct Dr Frank H. Lehey

Obliterative Cholangitis Involving the Extrahepatic Bile Ducts Dr Horace K. Sowles

Surgical Complications of the Salmonella Suispastifer Dr Irving Walker

Congenital Diaphragmatic Hernia in Children Dr Philemon E. Truesdale

At five o'clock the members and their wives were entertained by Dr and Mrs David W Parker at tea.

The eighteenth annual dinner was held at the Manchester Country Club. Eighty-three men sat at the table. After dinner the President Dr Peer P Johnson read an address and later introduced Mr Henry Wise Wood who spoke interestingly and at some length concerning canoeing sailing (the Cruising Club of America) and into the clouds by aeroplane and otherwise

At nine o'clock on Saturday morning the members assembled at the Carpenter again and at the annual business session elected the following of ficers

President Daniel C Patterson M.D. Bridgeport, Conn.

Vice-President David W Parker M.D. Manchester N H

Secretary John M. Birnie, M.D. Springfield Mass

Treasurer James R. Miller M.D., Hartford Conn.

Recorder Walter G. Phippen M.D., Salem Mass.

Executive Committee Officers of the Society Lucius Kingman M.D. Philemon E. Truesdale M.D. William H. Bradford M.D. Thomas W. Luce M.D. Lyman Allen, M.D.

It was announced that the next meeting would be held in Bridgeport, Connecticut.

Thereafter the following papers were read

A Form of Sclerosing Osteomyelitis following Fractures of the Long Bones Dr Paul P. Swett

Statics of the Foot in Relation to Surgery Dr Frederic J. Cotton.

DeQuervain's Disease and Carpal Ganglia, Dr Daniel C. Patterson.

Certain Aspects of Hand Surgery Dr Torr W. Harmer

Congenital Absence of the Pericardium Dr William E. Ladd

Urologic Aspects of Vesicovaginal Fistula Dr William C. Quinby

Acute Arterial Obstruction from Arteritis Dr Howard M. Cline

Personal Experience with Cancer of the Bladder Dr J. Dellinger Barney

Reconstruction of the Vagina from a Portion of the Sigmoid Report of a Case Dr Herman C. Pitts.

Everyone agreed that again a most interesting and instructive meeting had been enjoyed and that many thanks were due to the Manchester men for their thoughtful preparation. Over ninety men were present at the meeting

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance) Tuesday evening October 22 at 8 15 P.M.

PROGRAM

Presentation of Cases.

Some Experiences During a World Tour By Walter B. Cannon M.D.

MARSHALL N. FULTON M.D. Secretary

ESSEX NORTH DISTRICT MEDICAL SOCIETY

The Quarterly Meeting of the Essex North District Medical Society will be held Wednesday October 23 1935 at 1 00 P.M., at Peabody House Andover Academy

Business meeting will precede the luncheon which follows at Phillips Inn at 2 00 P.M.

Returning to Peabody House discussions will be presented by each of the city committees on mutual local problems of the profession and the public.

Dr Gaylord Anderson of the State Department of Health will discuss mutual problems of the Department of Public Health and the medical profession

E. S. BAONALL, M.D., Secretary

NEW ENGLAND PHYSICAL THERAPY SOCIETY

The first fall meeting of the New England Physical Therapy Society will be held in Parlor C the mezzanine, Hotel Statler Boston at 8 o'clock in the evening of Wednesday October 16 1935

PROGRAM

The Treatment of Hemorrhoids Leland S. McKittick M.D., Boston

Discussion will be opened by Vernon O. Stewart, M.D., Woburn and William D. McFee, M.D. Boston.

Preceding the meeting there will be an informal dinner in the main dining room of the Hotel Statler at six thirty. Those planning to attend will meet on the mezzanine

Members please take note of the change of meeting place

Physicians are cordially invited to attend

WILLIAM D McFEE, M.D., *Secretary*,
Boston, Mass

WORCESTER NORTH DISTRICT MEDICAL SOCIETY

The Worcester North District Medical Society will hold its next quarterly meeting at the State Colony in East Gardner, on Wednesday, October 23, at 4 30 P M Dr Charles E Mongan, President of the Massachusetts Medical Society, will be the guest speaker Luncheon.

FRANCOIS M McMURRAY, M.D., *Secretary*

TRUDEAU SOCIETY

The meeting of the Trudeau Society will be held at Rutland State Sanatorium on Tuesday, October 15, 1935, at 4 P.M. Dr Gulli Lindh Muller will read a paper on "Blood Studies in Relation to Surgery and Pulmonary Tuberculosis" Dr Paul Dufault will discuss "Pneumolysis Failures With Illustrations" There will be a moving picture entitled "The Sanatorium" The meeting will be opened by Dr John S Harter of the Lahey Clinic Lunch will be served at 6 30 P.M

MOSES J STONE, M.D., *Secretary*

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, OCTOBER 14, 1935

Monday, October 14—

BOOK REVIEW

National Medical Monographs Obstetrics for the General Practitioner J P Greenhill 304 pp
New York National Medical Book Company, Inc
\$3 00

This volume, in the series of National Medical Monographs, aims to present a survey of the field of clinical obstetrics in sufficiently compact form to be available as a manual for the busy practitioner. No attempt is made, therefore, to discuss the anatomic and embryological aspects of the subject. Beginning with prenatal care, the principal topics considered are those of abortion and miscarriage, premature labor, ectopic pregnancy, the toxemias and other complications of pregnancy, the management of normal labor, forceps delivery, Caesarean section, anesthesia, infections, and postpartum care. It is surprising that podalic version is dismissed with only the briefest description. One may also question the categorical statement that "low cervical Caesarean section is far safer than the classic operation." The volume is well illustrated with a series of thirty-nine cuts from DeLee's "Principles and Practice of Obstetrics"

The New England Journal of Medicine

NUMBER 16

THE USE OF DILAUDID IN TREATING PATIENTS WITH CANCER*

BY IRA T. NATHANSON, M.D.,† AND ERNEST M. DALAND, M.D.†

THE treatment of pain in the patient with malignancy has always been a difficult problem. The average practitioner feels that advanced cancer and large doses of morphine go hand in hand. Too often is the patient given a box of morphine tablets with instructions to use them as he needs them. We believe that a patient is no judge of the quantity needed or the time interval between doses and we have been impressed with the small amounts of medication needed if it is given under close supervision. Our policy is to relieve pain as far as possible by salicylates and barbiturates before resorting to opiates. We then turn to codeine alone or a combination with the above. Finally we resort to the stronger opiates, chiefly morphine.

Careful cleansing of ulcerated lesions, judicious use of deep x ray, minor surgical procedures (removal of sequestra, etc.) and careful nursing are greater factors in relieving pain than is the administration of medicines. Certain neurosurgical measures as chordotomy (severing the spinothalamic tract), rhizotomy, division of peripheral nerves and alcohol injection of nerves may remove all need for the administration of narcotics. The opiates are used and are necessary as preoperative and postoperative medication in the cancer patient treated surgically. When deep x ray therapy is used for treatment of the disease, the discomfort is increased for a time as the reaction develops and consequently there is need for more medication. In both of these groups, the operative case and the patient treated with maximum dose of x ray, it is hoped that the need for medication is but temporary. We desire, therefore, to use an agent that is not to become habit forming.

There is another group of patients suffering either from necrosis, edema, or replacement fibrosis following radiation, or from extensive involvement of bone, fascia or abdominal viscera from the extension of metastases where pain lasts as long as the patient lives. Granted that these patients need opiates, it is obvious that a drug should be selected which will not produce a rapidly increasing tolerance.

Each year sees the introduction of new drugs to replace morphine. One by one they disappear until we have codeine, morphine and pantopon as the only reliable narcotics. Within the past few years, another drug, dilaudid, has been advanced as a substitute for morphine because it is supposed to possess certain advantages over the latter. It has been said to be a "stronger analgesic, requiring but a small dose, about one-fifth that of morphine. It acts more quickly and is less likely to produce undesirable side effects."¹ In therapeutic doses, it is stated that it has very little hypnotic action.

Before discussing dilaudid, let us consider the more common disadvantages and side effects of morphine. Morphine is habit forming and a tolerance for it is gained rather rapidly. Constipation is practically a universal result of its use. Loss of appetite, nausea and vomiting, particularly in the operative cases, are common. Euphoria is prominent and there is marked hypnosis. Does dilaudid have fewer disadvantages?

Through the courtesy of the Bilhner Knoll Corporation, distributors of dilaudid, we were able to obtain a sufficient quantity for clinical trial. Dilaudid is the hydrochloride of a hydrogenated ketone of morphine and has the chemical name dihydromorphinone hydrochloride. It was first studied by Gottlieb in 1926 who found that the effective dose was considerably smaller than that of morphine, the action set in more quickly, and there was less interference with intestinal peristalsis. This work was done with animals, although a clinical report was made by Krehl. Since that time the foreign literature has contained numerous articles on the subject.

The Committee of Experts² appointed by the Council of the League of Nations in May, 1931, in reporting on heroin states, "For the relief of pain in patients in whom it is undesirable to act on the bowels, heroin is better than morphine, but dilaudid offers the same advantages. Dilaudid has a slightly weaker effect on the respiratory center than heroin, it has the same analgesic effect as heroin, both drugs have little effect on the alimentary canal. The euphoric effects of dilaudid are weaker than both morphine and heroin as gauged by withdrawal symptoms. It was not until 1932, however, that Alvarax³ introduced it in the United States. His experience was that the drug had the same prop-

From the Fowdville Hospital, Massachusetts Department of Public Health, Wrentham, Massachusetts.

*Nathanson, Ira T.—Formerly Surgical Resident, Fowdville Hospital, Wrentham. Daland, Ernest M.—Chief of Staff, Fowdville State Cancer Hospital. For records and addresses of authors see "This Week's Issue," page 774.

erties of codeine with the additional ones of being a much better reliever of pain, and being without effect on the bowels. He did not find that it entirely removed the nauseating and emetic effects of morphine.

Eddy⁴ at the request of the Council on Pharmacy and Chemistry of the American Medical Association reported on the general status of the alkaloid, and made an extensive review of the literature. Experimentally, he found it to be powerfully analgesic but that, like morphine, it depressed respirations, and that the established ratio between effective doses of morphine and dilaudid for production of desirable effects was not materially different from the ratio between their toxic doses. He did not believe that dilaudid was free from tolerance and addiction evoking properties although side reactions seemed to occur less frequently. He advised that prolonged administrations should be made as cautiously as with morphine.

Menard⁵ felt that dilaudid was more desirable than morphine because it was better tolerated, produced more effective analgesia in smaller doses and caused fewer undesirable symptoms.

Paine et al⁶, in studying postoperative nausea vomiting and distention, found that while dilaudid was effective in relieving the postoperative pain, it showed no marked advantages over morphine, and stressed the possibility of respiratory depression.

David⁷ states that in therapeutic doses, dilaudid tended to lower the basal metabolic rate as did morphine, but that it acted more rapidly and over a shorter period of time. He believed it to be ten times as active as morphine. In regard to tactile discrimination and respiratory depression, it was slightly superior to morphine. As to the side effects it appeared to produce less euphoria, more diarrhea and more itching.

Stroud⁸ found dilaudid to be efficient in control of constant pain, and considered it superior to any other opiate as regards analgesic effects and side reactions. He advised that it be administered with sufficient frequency to permit continuous effect.

Weum⁹ used dilaudid in labor, postpartum and postoperatively. He believes that it excels both morphine and codeine in postpartum or postoperative care especially when administered in the form of the rectal suppository.

Dilaudid was administered in various dosages, forms and combinations to 115 cases of malignant disease at the Pondville Hospital. The site and nature of the lesion is indicated in table 1. In fifteen other cases the drug was used as a pre- and postoperative medication a like number of similar cases being given morphine to serve as controls. The indications for the medication were the same as that for the other opiates. It was given regardless of whether they had previous opiates, and if it was known that they had detailed questions

were asked to determine the dosage, the duration of administration, and the analgesic and side effects so that a favorable comparison could be made. All of the patients were observed and questioned by one of us, but additional information was obtained from members of the house staff, the nursing personnel and the house records. The patients were asked no leading questions, and they did not know the nature of the drug they were receiving. The points, upon

which stress was laid by whatever route the drug was given, were rapidity of action, degree of analgesia, duration of analgesia, the intervals between doses, the hypnotic action, the effect on the gastrointestinal tract (loss of appetite, nausea, vomiting, constipation and diarrhea), the other side reactions, and the question of tolerance where possible.

It may be well to state here that, at the Pondville Hospital, the patient is started on a minimal amount of drug necessary to control pain, regardless of the amount and type of medication received elsewhere. The dosage is increased, or medication altered only because of increased tolerance or pain, or because of very undesirable side effects. It is interesting to note that by judicious use of the drug, the patients can be made comfortable on relatively small doses for long periods of time. Consequently, upon eradication of the disease, and even with terminal care patients, the dose is never large. In the former group they are almost always discharged without need for opiates as the amount is gradually lessened as the disease is alleviated with very little evidence of withdrawal symp-

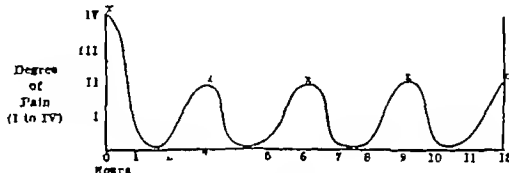

toms, as to the latter, we seldom have to resort to massive doses to control pain, even in the end stages of the disease. Because of this fact, we have seen surprisingly less evidence of tolerance or habituation during their stay in the hospital than one would expect. If these symptoms are observed on admission, every attempt is made to eradicate them. In the evaluation of the effect of any medication for the relief of pain one must take into consideration the duration, the degree, the location and the type of pain if one wishes to make a satisfactory observation. Consequently, when this study was undertaken, these factors were kept in the foreground in the estimation of our results.

Dilaudid was given by mouth, by hypodermic injection by suppositories, and in combination

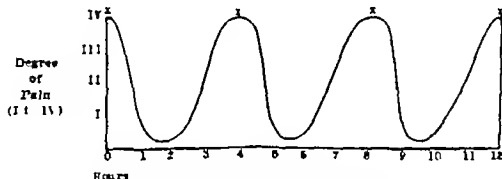

codeine. The dilaudid dosage varied from grains 1/64 to 1/20 by hypodermic injection and from grains 1/48 to grains 1/24 by oral administration. Codeine varied from grains 1/2 to grains 1, and morphine from grains 1/8 to grains 1/2. The medication was administered with sufficient frequency to permit continuous relief, i.e., it was repeated before the pain had again reached its maximum intensity. If used in this way it will be found that the single dose necessary to produce satisfactory analgesia will be smaller and more effective although the total amount in twenty-four hours may be the same as larger doses given at less frequent intervals when the pain is at its height.

The following graphs have been made diagrammatically to illustrate the point

Smaller Doses

Larger Doses

X = time at which medication is given

with synergistic drugs as aspirin and pyramidon (the latter has not been used in the past six months because of the many reports in the literature of granulocytopenia apparently resulting from it) in much the same manner as we used morphine and codeine. As soon as a case was admitted, a history of the amount and effect of previous medication if any, was taken. In one group if an opiate was necessary the patient was then placed on the amount of codeine or morphine to relieve his pain satisfactorily. After a variable period, when an evaluation of the effect of the medication could be made, he was given dilaudid in the equivalent doses as recommended by various writers, that is, one-fifth that of morphine. In other cases where no medication other than a non-narcotic was given he was placed on dilaudid directly, and the observations recorded. A control group was made up of patients who without previous narcotic medication were placed on morphine or

Observations. The following actions of dilaudid as compared with that of other opiates have been noted. Dilaudid either by mouth or by hypodermic is approximately twice as rapid in action as that of other drugs. Its effect was evident almost invariably before a fifteen minute period and it usually took effect in about ten minutes. The duration and degree of relief varied directly with the dose given and the amount of pain. It compared very favorably with morphine (Case 6). In some instances it appeared to be more efficacious (Case 8), although the reverse was also true.

In the doses given very little hypnotic action was seen although in a few cases a "dopiness" was observed. It was necessary, therefore to supplement the dilaudid with a barbiturate in those patients who could not sleep even when they experienced complete relief from pain (Case 9). In individuals who had had morphine or codeine previously it was found that although

1 with aspirin grains 10 was given with more satisfactory relief for three hours. Finally, dilaudid grains 1/24 with aspirin grains 10 was administered giving complete relief for four hours.

CASE 8 D B Aged twenty—Pondville No 6541 Lymphoblastoma involving skin, lymph nodes and lumbar vertebrae. The patient complained of generalized pain especially in the groins, chest and back, usually dull but intermittently sharp. Medication previous to admission was aspirin. On entry she was placed on morphine grains 1/4 subcutaneously every four hours over a period of a week. The latent period was thirty minutes, relief was complete for two and one-half hours with moderate hypnosis. Constipation was marked. She was then given dilaudid grains 1/20 by hypodermic for a similar period. The latent period was ten minutes with complete relief from pain until the next dose (i.e., four hours). There was no hypnosis and constipation was much relieved. Morphine was resumed, but the dose had to be given every three hours with not such satisfactory relief as with dilaudid and constipation again became severe.

CASE 9 M E Aged sixty—Pondville No 7480 Carcinoma of the cervix with frozen pelvis. The symptoms consisted of excruciating pain in the pelvis radiating down the legs. No medication before entry. On admission she was given codeine grains 1 with pyramidon grains 10 over a period of six days on an average of every three hours. Relief was partial for two hours. Dilaudid grains 1/24 was given by mouth for a daily average of every four hours over a week. The action was quicker and

she experienced complete relief for periods varying from four to six hours, but required a barbiturate in addition at night for sleep.

CASE 10 N B Aged forty seven—Pondville No 7299 Total hysterectomy for carcinoma of fundus. Anesthesia, ether by cone method. Preoperative medication dilaudid grains 1/20 with atropine grains 1/150. Fifteen minutes after administration the respirations decreased from an average of 20 to 8, and became very shallow with development of cyanosis. Stimulation with carbon dioxide and oxygen for cyanosis was necessary throughout the operation. Relaxation was not successfully obtained and the operative procedure therefore was made more difficult and was prolonged.

MUSCLE GRAFTS FOR HEMOSTASIS IN GENERAL SURGERY

BY HOWARD M. CLUTE, M.D.*

FREE muscle tissue has a marked ability to control the oozing of small vessels by hastening the formation of blood clot. Harvey Cushing¹ noted this quality in muscle and made use of it in controlling bleeding vessels during brain tumor operations. Victor Horsley², however, is given credit by Cushing for his earlier use of this method which Cushing had independently worked out.

The application of this clot-hastening quality of muscle grafts was limited to the field of brain and cord surgery for many years and has not yet been adopted to any degree by general surgeons. Risley in 1917³ published the results of experimental work in which he tried muscle fat and fascia as hemostatic agents to control bleeding from parenchymatous organs. He found that both fat and fascia have hemostatic effects, but that muscle tissue was most effective. Risley recommended the use of muscle tissue to control bleeding in wounds of the liver, kidney, and possibly of the spleen. Lawen⁴ discussed the use of muscle grafts as hemostatic agents in 1912 and reported upon their use in two heart wounds in 1917.

Further application in surgery of this hemostatic property of muscle came from the urologists. Thus Ciminata⁵ in 1924 and Joseph⁶ in 1931 used the principle in the control of bleeding from nephrotomy wounds. In 1934 Ockerblad⁷ published the results of experimental and clinical work in the use of viable muscle grafts for the control of bleeding from the parenchyma of the kidney. This procedure of Ockerblad's is new in that he uses *viable* muscle grafts rather than detached or dead muscle transplants as previous workers had done. He believes that maintenance of the blood supply in the muscle graft reduces the danger of infection in the wound.

Muscle grafts are not infrequently of great value to the general surgeon in the control of oozing in the operative field. It has been repeatedly demonstrated to me that troublesome bleeding may be readily stopped by the use of free muscle grafts. In my clinical experience it has seemed that bleeding is equally well controlled by either a free or a viable muscle graft. When, therefore, a viable muscle graft is readily made, as in the bleeding from thyroid remnants, viable grafts are used. If, however, the bleeding comes from an area in which there is no adjacent muscle for transplantation, a

*Clute, Howard M. — Surgeon in Chief, II Surgical Service, Carney Hospital. For record and address of author see *This Week's Issue* page 776.

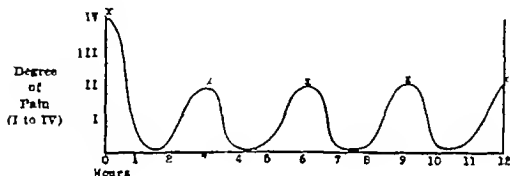

toms, as to the latter, we seldom have to resort to massive doses to control pain even in the end stages of the disease. Because of this fact, we have seen surprisingly less evidence of tolerance or habituation during their stay in the hospital than one would expect. If these symptoms are observed on admission, every attempt is made to eradicate them. In the evaluation of the effect of any medication for the relief of pain, one must take into consideration the duration, the degree, the location and the type of pain if one wishes to make a satisfactory observation. Consequently, when this study was undertaken, these factors were kept in the foreground in the estimation of our results.

Dilaudid was given by mouth, by hypodermic injection, by suppositories and in combination

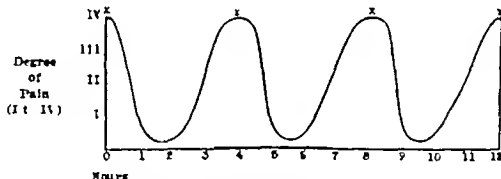

codeine. The dilaudid dosage varied from grains 1/64 to 1/20 by hypodermic injection and from grains 1/48 to grains 1/24 by oral administration. Codeine varied from grains 1/2 to grains 1, and morphine from grains 1/8 to grains 1/2. The medication was administered with sufficient frequency to permit continuous relief, i.e. it was repeated before the pain had again reached its maximum intensity. If used in this way it will be found that the single dose necessary to produce satisfactory analgesia will be smaller and more effective although the total amount in twenty four hours may be the same as larger doses given at less frequent intervals when the pain is at its height.

The following graphs have been made diagrammatically to illustrate the point

with synergistic drugs as aspirin and pyramidal (the latter has not been used in the past six months because of the many reports in the literature of granulocytopenia apparently resulting from it) in much the same manner as was used morphine and codeine. As soon as a case was admitted a history of the amount and effect of previous medication, if any, was taken. In one group if an opiate was necessary the patient was then placed on the amount of codeine or morphine to relieve his pain satisfactorily. After a variable period, when an evaluation of the effect of the medication could be made, he was given dilaudid in the equivalent doses as recommended by various writers that is, one-fifth that of morphine. In other cases where no medication other than a non-narcotic was given he was placed on dilaudid directly, and the observations recorded. A control group was made up of patients who without previous narcotic medication were placed on morphine or

Observations. The following actions of dilaudid as compared with that of other opiates have been noted. Dilaudid either by mouth or by hypodermic is approximately twice as rapid in action as that of other drugs. Its effect was evident almost invariably before a fifteen minute period and it usually took effect in about ten minutes. The duration and degree of relief varied directly with the dose given and the amount of pain. It compared very favorably with morphine (Case 6). In some instances it appeared to be more efficacious (Case 8), although the reverse was also true.

In the doses given very little hypnotic action was seen although in a few cases a "dopiness" was observed. It was necessary therefore, to supplement the dilaudid with a barbiturate in those patients who could not sleep even when they experienced complete relief from pain (Case 9). In individuals who had had morphine or codeine previously, it was found that although

they admitted satisfactory relief from pain with dilaudid, they did not care for the drug because it did not give them the usual feeling of well-being or have the hypnotic effect to which they had become accustomed. This weaker hypnotic effect is of definite benefit to the ambulatory patient, as it gives him the opportunity to be up and around, and aware of his surroundings.

The effect on the gastrointestinal tract in our experience was found to be superior to that of morphine or codeine as regards the side actions. The appetite was seldom diminished, and constipation although present in a fair number of cases, was not so severe as from the other drugs. Nausea and vomiting which are not infrequently seen after morphine, were seldom noted, although they did occur occasionally with the administration of dilaudid (Case 1).

Other effects. It was noted that an appreciable number complained of transient dizziness or giddiness within a few minutes after the hypodermic injection. This was not noted after morphine. Itching was a much more frequent symptom than with the other opiates. Euphoria was seen in but a few cases, but in respect to this, we can make no comparison, as it was seldom noted with the doses of morphine that were used. Respiratory depression was observed more frequently from therapeutic doses than from corresponding doses of morphine. In one instance, death is believed to have occurred from it (Case 2). This depression was found to be especially evident when the drug was used preoperatively, and occurred during the administration of the anesthetic (Case 10) but it was also seen during the administration of the drug for pain especially with the first few doses.

The question of tolerance is an important one, and we believe that patients receiving dilaudid, although they do become tolerant, are less likely to become so than with morphine. This is evidenced by the fact that it is possible to continue the cases on the same doses for a much longer time, once the effective dose has become established, than with effective doses of the other opiates. In respect to habituation, we have not seen it, but this is most likely due to the fact that the drug was not given for a sufficient length of time. We have no reason to believe that the drug is not habit forming. Withdrawal symptoms when the patients had definitely become tolerant, were milder than those seen with morphine. However, with the mode of administration used at Pondville, tolerance is increased very slightly even with morphine, so that withdrawal symptoms in general are relatively infrequent.

In a group of patients who had received morphine or codeine for a considerable period (i.e., two weeks or more) prior to or after admission, the effects of dilaudid in equivalent doses in

most instances were not nearly so efficacious as the drug previously administered. The reverse was not always true. It is felt that this is definitely due to cross tolerance (Case 5). Substitution therapy with dilaudid in definite cases of morphine addiction was unsuccessful in our hands.

In this series of cases, morphine was found to be more consistent in its action than dilaudid. Dilaudid was more consistent than codeine, but when codeine was given in combination with aspirin, it was found to be more efficacious than equivalent doses of dilaudid. However, when aspirin was given with dilaudid, it was observed that this combination was much superior to the codeine and aspirin. Grams 1/48 of dilaudid with aspirin grains 10 was more efficient than codeine grains 1/2 and aspirin grains 10, and in some instances was equal to or better than codeine grains 1 and aspirin grains 10 in its action. This suggests, therefore, an efficient analgesic with a relatively small dose of a narcotic for patients suffering from moderate pain (Case 7).

The rectal suppository was felt to be superior to an equivalent dose of an opiate suppository in that its action was more rapid, and lasted longer. It is especially suitable for cases of carcinoma of the rectum, and carcinoma of the cervix, with invasion of the rectovaginal septum (Case 3).

Cough. Many writers have suggested its use in postoperative cough, in cough due to pulmonary metastases and the irritative type from lesions of the oral cavity, pharynx and larynx. We have found it to be very efficient and definitely superior to codeine. In combination with terpene hydrate it is especially efficacious (Case 4).

Preoperative and Postoperative Use. In a series of fifteen cases, dilaudid was used as a preoperative medication in combination with atropine in an effort to determine its efficiency as a preoperative drug. It was used postoperatively also to determine the effects on postoperative nausea, vomiting, and distention. The cases ranged from short anesthetics to ones requiring complete relaxation and longer anesthesia. A comparable number were observed as controls in which morphine was used as a preoperative and postoperative medication. Although the series is much too small for any conclusions, the observations seem to indicate the following: Dilaudid tended to cause more respiratory depression, thereby causing a more difficult anesthesia. In two instances, the respirations fell to 8, and stimulation with carbon dioxide and oxygen was necessary. It was found that the degree of relaxation necessary for any given type of operative procedure was less easily obtained than with morphine. The incidence of postoperative nausea and vomiting was definitely less in the dilaudid group. It was espe-

cally noted that relatively few patients vomited immediately upon awakening or after cessation of anesthesia as they did with morphine. Used postoperatively, it was a very efficient analgesic, but some cases required barbiturates to obtain sleep. So far as postoperative distention is concerned, the degree of difference was not sufficient to permit any definite conclusions. In general, however, gas was passed earlier by three patients than by those with morphine and it had less constipating effect (Case report 10).

For detailed observations see tables 2 and 3.

Summary. Dilaudid is an efficient analgesic in doses approximately one-fifth those of morphine. Its speed of action is about twice as fast as that of the other opiates and its duration of action and degree of relief compare favorably with that of morphine. It is not usually hypnoctic in therapeutic doses, and requires in many instances the addition of a barbiturate to obtain sleep. The effect on the gastrointestinal tract as regards side reactions is less than that of morphine. It is an efficient reliever of cough due to various causes. It is less likely to produce undesirable side effects than morphine, but on the other hand, itching and respiratory depression seem to be more prominent. Its efficiency in combination with other drugs has been demonstrated. Tolerance, although it is believed to develop, is not so marked or rapid as with morphine. It is not so efficient as the other opiates when it is given in equivalent doses after the other opiates are used first for a period of several weeks at least. This was felt to be due to cross tolerance. Its effect pre- and postoperatively has been discussed from a small series of cases. The mode of administration is important, and it was found that small doses at frequent intervals were superior to large doses at less frequent intervals although the total twenty-four hour amount may have been approximately the same.

Conclusion. There is a definite place for the use of dilaudid in the armamentarium available for the treatment of pain in cancer patients, but it must be used with the same caution as the other opiates.

CASE REPORTS

CASE 1. L. M. B. Aged thirty-eight.—Pondville No 3146. Carcinoma of both breasts with pleural metastases. Complained of pain in the chest. She was given codeine pantopon and morphine followed by excessive emesis in every instance. Dilaudid was then given both by mouth and by hypodermic with the same results. This case demonstrates a definite idiosyncrasy to any type of opiate.

CASE 2. D. H. Aged seventy-six.—Pondville No 5506. Carcinoma of buccal mucosa operative excision under local anesthesia. Preoperative medication morphine grains $\frac{1}{4}$ with atropine grains $\frac{1}{150}$ at 3:30 P. M. one-half hour before operation. No unusual reaction was noted and operation was uneventful. At 7:30 P. M. the patient complained of

pain and was given dilaudid grains $\frac{1}{32}$ subcutaneously—twenty minutes later he developed marked cyanosis, respirations dropped to eight per minute, pupils were small, pulse was 100 and he could not be roused. Skin was warm and dry. Caffeine sodio-benzoate grains $\frac{7}{16}$ was given in conjunction with oxygen-carbon dioxide inhalations with relief of cyanosis, rise in respiratory rate to 15 and an increase in depth. Condition fair for about one-half hour. Then he lapsed into profound cyanosis, respirations were shallow and decreased to an average of four per minute, pulse 88 and pupils were pinpoint. He did not respond to any type of stimulation including coramine and oxygen and carbon dioxide inhalation. Artificial respiration was necessary and was continued for one-half hour in spite of which death ensued. This is believed to be a case of respiratory paralysis initiated by the administration of dilaudid.

CASE 3. G. A. M. Aged forty-nine.—Pondville No 7742. Inoperable carcinoma of the rectum with colostomy. The patient complained of tenesmus and pain in both legs. Dilaudid suppositories (grains $\frac{1}{24}$) were administered with complete relief of symptoms. Later he was given opium suppositories (grains 1) with only partial relief for a shorter period of time. Dilaudid then was resumed with excellent results.

CASE 4. J. T. Aged seventy-three.—Pondville No 8527. Carcinoma of tonsil and soft palate. This patient developed a bad cough after x-ray treatment. It was especially severe at night. He was given codeine grains 1 with only partial relief and continued to have paroxysms. He was then given dilaudid grains $\frac{1}{24}$ which gave him complete relief and allowed him to sleep.

CASE 5. T. J. L. Aged sixty-two.—Pondville No 7443. Epidermoid carcinoma of left temporo-occipital region involving mastoid cells. The patient complained of pain in the left head and face. He was given codeine grains 1 and aspirin grains 10 for a period of three weeks on an average of three times daily. The latent period of action was between one-half and one hour. He was completely relieved for four hours. Dilaudid grains $\frac{1}{24}$ was then given by mouth for an average of four times daily for a period of six days. Relief was only partial for two and one-half hours although the latent period of action was only fifteen minutes. Dilaudid grains $\frac{1}{32}$ was then administered by hypodermic, with approximately the same results. Codeine and aspirin were then resumed with the same results as originally.

CASE 6. C. K. Aged fifty-nine.—Pondville No 5350. Carcinoma of right cheek involving nose, antrum and orbit. The patient complained of continuous sharp pain in that area. Previous to entry she took only aspirin. On admission morphine grains $\frac{1}{6}$ hypodermically was found to be the effective dose. It was required on the average of four times daily and gave complete relief for four to five hours with moderate hypnosis and a latent period of one-half hour. Dilaudid grains $\frac{1}{32}$ was then given for six days with a daily average of four doses. The latent period was fifteen minutes and complete relief was obtained for four hours without hypnosis. In this case the effects of the drugs appeared to be about the same.

CASE 7. R. V. Aged forty-five.—Pondville No 6719. Carcinoma of cervix with frozen pelvis. There was pain in the pelvis and legs. Dilaudid grains $\frac{1}{24}$ was given orally with partial relief for two hours over a period of two weeks. Then codeine grains

1 with aspirin grains 10 was given with more satisfactory relief for three hours. Finally, dilaudid grains 1/24 with aspirin grains 10 was administered giving complete relief for four hours.

CASE 8 D B Aged twenty—Pondville No 6541 Lymphoblastoma involving skin, lymph nodes and lumbar vertebrae. The patient complained of generalized pain especially in the groins, chest and back, usually dull but intermittently sharp. Medication previous to admission was aspirin. On entry she was placed on morphine grains 1/4 subcutaneously every four hours over a period of a week. The latent period was thirty minutes, relief was complete for two and one-half hours with moderate hypnosis. Constipation was marked. She was then given dilaudid grains 1/20 by hypodermic for a similar period. The latent period was ten minutes with complete relief from pain until the next dose (i.e., four hours). There was no hypnosis and constipation was much relieved. Morphine was resumed, but the dose had to be given every three hours with not such satisfactory relief as with dilaudid and constipation again became severe.

CASE 9 M E Aged sixty—Pondville No 7480 Carcinoma of the cervix with frozen pelvis. The symptoms consisted of excruciating pain in the pelvis radiating down the legs. No medication before entry. On admission she was given codeine grains 1 with pyramidon grains 10 over a period of six days on an average of every three hours. Relief was partial for two hours. Dilaudid grains 1/24 was given by mouth for a daily average of every four hours over a week. The action was quicker and

she experienced complete relief for periods varying from four to six hours, but required a barbiturate in addition at night for sleep.

CASE 10 N B Aged forty seven—Pondville No 7299 Total hysterectomy for carcinoma of fundus. Anesthesia, ether by cone method. Preoperative medication dilaudid grains 1/20 with atropine grains 1/150. Fifteen minutes after administration the respirations decreased from an average of 20 to 8, and became very shallow with development of cyanosis. Stimulation with carbon dioxide and oxygen for cyanosis was necessary throughout the operation. Relaxation was not successfully obtained and the operative procedure therefore was made more difficult and was prolonged.

MUSCLE GRAFTS FOR HEMOSTASIS IN GENERAL SURGERY

BY HOWARD M. CLUTE, M.D.*

FREE muscle tissue has a marked ability to control the oozing of small vessels by hastening the formation of blood clot. Harvey Cushing¹ noted this quality in muscle and made use of it in controlling bleeding vessels during brain tumor operations. Victor Horsley², however, is given credit by Cushing for his earlier use of this method which Cushing had independently worked out.

The application of this clot-hastening quality of muscle grafts was limited to the field of brain and cord surgery for many years and has not yet been adopted to any degree by general surgeons. Risley in 1917³ published the results of experimental work in which he tried muscle fat and fascia as hemostatic agents to control bleeding from parenchymatous organs. He found that both fat and fascia have hemostatic effects, but that muscle tissue was most effective. Risley recommended the use of muscle tissue to control bleeding in wounds of the liver, kidney, and possibly of the spleen. Lawen⁴ discussed the use of muscle grafts as hemostatic agents in 1912 and reported upon their use in two heart wounds in 1917.

Further application in surgery of this hemostatic property of muscle came from the urologists. Thus Cimminata⁵ in 1924 and Joseph⁶ in 1931 used the principle in the control of bleeding from nephrotomy wounds. In 1934 Ockerblad⁷ published the results of experimental and clinical work in the use of viable muscle grafts for the control of bleeding from the parenchyma of the kidney. This procedure of Ockerblad's is new in that he uses *viable* muscle grafts rather than detached or dead muscle transplants as previous workers had done. He believes that maintenance of the blood supply in the muscle graft reduces the danger of infection in the wound.

Muscle grafts are not infrequently of great value to the general surgeon in the control of oozing in the operative field. It has been repeatedly demonstrated to me that troublesome bleeding may be readily stopped by the use of free muscle grafts. In my clinical experience it has seemed that bleeding is equally well controlled by either a free or a viable muscle graft. When, therefore, a viable muscle graft is readily made, as in the bleeding from thyroid remnants, viable grafts are used. If, however, the bleeding comes from an area in which there is no adjacent muscle for transplantation, a

*Clute, Howard M. — Surgeon in Chief, II Surgical Service, Carney Hospital. For record and address of author see "This Week's Issue," page 775.

piece of free muscle has been used with equal success and with no later complications.

Since my attention has been directed to the value of this method for the control of bleeding numerous opportunities have arisen for its use. The first was in a patient with a very large and badly adherent pyonephrosis. During the course of the removal of this kidney the vena cava was torn. With considerable difficulty the hole in the vena cava was caught with a fine silk suture. This did not control the oozing, and therefore a piece of muscle tissue was laid over the wound in the vein and held in place lightly with a suture (Fig. 1). This effect-

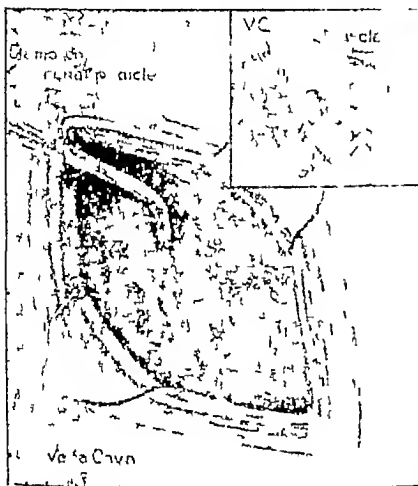

FIG. 1. Longitudinal tear in the vena cava in the course of nephrectomy. Silk suture in the sin did not entirely control the bleeding. A small piece of muscle tissue lightly held in place gave complete control.

tively controlled the bleeding and the patient made an excellent postoperative recovery.

Bleeding from the cut surface of the thyroid gland may be very difficult to control. Usually this type of hemorrhage is readily managed by ligation of the superior and the inferior thyroid arteries combined with the pressure made by folding the thyroid remnant over to the midline. Occasionally the remnant of thyroid is so indurated that it cannot be folded over with sutures and the ooze cannot be readily controlled. It has been the practice in the past to control this persistent oozing by placing a cigarette drain down to the bleeding area. This, I believe, can be largely avoided by the use of both free and viable grafts of muscle tissue. The edges of the sterno-thyroid muscle are readily available for grafting into the remnant of thyroid gland. If they do not adequately and

completely control the bleeding, small free grafts from the adjacent sternomastoid muscle can be placed over the thyroid remnant (Fig. 2). Usually one feels more secure if these grafts are held in place with fine catgut sutures. These grafts of muscle tissue have frequently made the field so dry that not even rubber dam drainage was necessary. No infection in these cases has been observed.

In one instance a free muscle graft proved very useful in controlling the bleeding from a tear in the internal jugular vein. Here, of course, control of bleeding is easier than in tears of the vena cava and if need be, one can ligate the entire vein above and below the injury. In this case, however, the jugular was very large

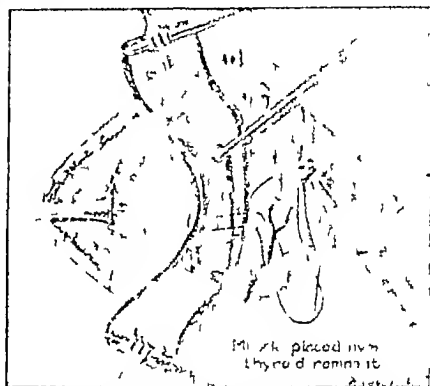

FIG. 2. Thyroid remnant after thyroidectomy occasionally oozes persistently in spite of ligation of the major thyroid arteries. The border of the sterno-thyroid muscle serves as a reliable muscle graft to control bleeding. A free muscle graft occasionally a necessary additional help and makes the use of packs and drains unnecessary.

and the tear was low and partly under the clavicle. Silk sutures were placed in the wall of the jugular and reinforced with a free graft of muscle tissue. The result was entirely satisfactory.

It is the experience of every abdominal surgeon that large oozing areas occasionally are present following the removal of certain pelvic tumors. In a recent case the patient had a very large right-sided intraligamentous ovarian cyst in which there was malignant degeneration. Following its removal persistent oozing arose from the layers of the broad ligament and the lateral wall of the pelvis. Attempts to catch individual bleeding points were unsatisfactory and the close proximity of the rectum made the procedure hazardous. Free muscle grafts were taken from the rectus muscle and laid in the bleeding area (Fig. 3). The peritoneum of the broad ligament was sutured over the bits of muscle and all bleeding was completely checked. Recovery was entirely uneventful.

Similarly, bleeding from the liver bed after cholecystectomy can be very neatly checked and large packs and drains avoided by the use of free muscle grafts. I have had no personal experience with the use of muscle tissue in ruptures of liver tissue, but both clinical and ex-

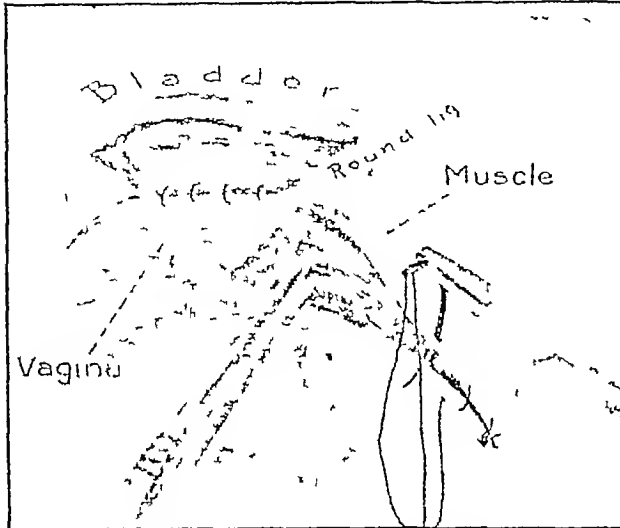

FIG 3 Troublesome bleeding in the pelvis not infrequently follows the removal of adherent tumors. Ties and ligatures may endanger the adjacent ureter. A free muscle graft will often serve admirably to control the oozing.

perimental evidence is at hand as to its usefulness in such cases.

It has been demonstrated by Ockerblad and others in animal experiments that viable muscle grafts are sufficient to control the bleeding from

an extensive nephrotomy wound. There may, no doubt, be occasional clinical situations where such a wound must be managed by this means, but these occasions will probably be rare. Usually the surgeon will insist that the control of the major portion of the bleeding in any operative field shall be by the orthodox methods already in use and only supplemented by the use of muscle grafts. Certainly in general surgery it would appear that the most helpful place for the hemostatic action of muscle grafts is in the small persistent ooze that defies control from the usual snap and tie method. Here it has a great deal of value and a field of application much wider than has previously been used.

THE NEW HAMPSHIRE MEDICAL SOCIETY

AMEBIASIS IN A RURAL COMMUNITY*

BY FRANK H. CONNELL, PH.D.†

IN discussing amebiasis, one finds himself immersed in a subject where loose use of terminology has been the rule rather than the exception. It will be time well spent, I believe, if we take a few minutes to define our terms, that we may all speak the same language.

As Craig (1934) points out, the term "amebiasis" really means an infection by any of the six species of amebae known to infect man. "Clinical amebiasis" on the other hand, means the invasion of the tissues of man by pathogenic or disease-producing amebae. The only ameba which actually invades tissues is *Endameba histolytica*. This invasion usually occurs in the mucous membrane of the large intestine, or much more rarely, through the lower portions of the small intestine.

The symptoms of such infections vary all the way from slight digestive disturbances to the most severe symptoms of amebic dysentery and liver abscess.

By the term, "amebic or tropical dysentery" is meant a bloody, mucoid diarrhea, caused by *Endameba histolytica*, as one of the manifestations of amebiasis. This is a most unfortunate choice of name. It has led to a confusion of ideas. In the first place, dysentery is only one of the many symptoms of amebiasis and a rare one at that. In the second place, amebiasis is not limited to the Tropics. The first recorded case, described by Loesch in 1875, was from Leningrad.

Let us consider the symptoms of amebiasis only in a very general way. My real purpose today is to acquaint you with the methods used in finding amebae, and to indicate their incidence in this region.

Dr French is much more experienced in the

*Read at the Annual Meeting of the New Hampshire Medical Society at Manchester N. H. May 7 1935

†Connell Frank H.—Assistant Professor Parasitology Dartmouth Medical School. For record and address of author see "This Week's Issue" page 775

manifestations of amebiasis than I and it is to him that I refer you for a more detailed account of Clinical Amebiasis

Let me impress upon you that no one can carry the amebae without harm. It is impossible for *Endameba histolytica* to live except at the expense of host tissues. While considering the symptoms arising from amebiasis, let us keep always before us the fact that here as in all parasitic infections, we have essentially a host-parasite relationship, the parasite living not wilfully, but of necessity, at the expense of its host, and the host, using all means within its power to destroy or adjust itself to its unwelcome guest.

The appearance of clinical symptoms is, then, indicative of the direction in which the tides of battle are running. When the host is strong and healthy, repairing the damage as fast as it is made, a carrier condition results for the duration of which normally formed stools are passed which contain thousands of the infective cysts of the ameba. Truly healthy carriers are very rare, as most infected persons, well over fifty per cent, show some symptoms.

As listed by Craig, such symptoms include abdominal pain, abdominal distention, constipation, diarrhea, disturbances of appetite, loss of weight, headache, sleepiness, poor memory, muscle aches, nervous irritability, fever, poor circulation, sallow skin. It is this carrier condition which occurs most commonly in our latitude. For some reason, unknown to us, dysentery is more common in tropical countries than here. Symptoms appear, on the average, about one hundred days after infection, but amebae can usually be demonstrated in stools within ten days after infection.

There are three methods by which amebae may be demonstrated in feces, by culture, by concentration or by direct microscopic examination. Choice of methods depends largely upon conditions. If but one specimen can be examined, the culture method is undoubtedly the best, revealing, as it does, about ninety per cent of all infections in any given group after one examination. Examination of one specimen by the concentration technique will usually uncover about seventy per cent of the infections, while a single examination by the direct microscopic method reveals only about forty per cent of the infections in any one group.

In my opinion, diarrheic stools which contain only motile amebae, should be examined whenever possible by both the culture and direct microscopic methods. In cases where formed stools are being passed, we feel that one method is as good as another, if there is no limit upon the number of stools that can be obtained, or the amount of time that can be expended upon such work. One must keep in mind that encyst-

ment seems to be of a cyclical nature, that thousands of cysts per gram of feces may be passed on one day and a very, very few on the next. If but a single examination can be made, we must then adapt our methods to the stool in order that the infection may not be missed if the cysts happen to be few in number.

The most important thing for clinicians to remember is that diarrheic stools should be examined almost immediately and formed stools as soon as possible, preferably within twenty-four hours. It may be of interest to you that in the handling of dysenteric stools, there can be no real danger of acquiring an amebic infection, as such stools contain only active or motile amebae, which are unable to pass the stomach. The mature infective cysts, found only in formed or semi-formed stools, are resistant to all ordinary germicides for considerable periods of time. The only adequate protection against them which has been found thoroughly practicable is a prolonged and thorough drying of the hands. Desiccation is one condition that cysts cannot stand. Ten minutes' use of a mechanical dryer will apparently kill cysts effectively.

The distribution of the causative organism of amebic dysentery, *Endameba histolytica*, is world-wide. Wherever men have looked for it, it has been found. The incidence is higher in unsanitized regions. The incidence varies among different classes of people, depending upon opportunity for infection, being highest among people of low economic status, travelers, and those living in institutions.

Picked at random from the literature we find the incidence in Java to be twenty-three per cent, New Zealand eleven per cent, the Mediterranean region seventeen per cent, Peking twenty per cent, England nine per cent, food handlers in Leningrad thirty-six per cent, Morocco forty per cent, house servants, Haiti fifty per cent, Yunnan twenty per cent, United States about ten per cent.

During the past three years, I have had the opportunity to make fecal examinations on sixty-three persons, living in and around Hanover, most of them patients of Dr. Harry French. In addition, during the past semester, I have been attempting a survey of the seven hundred Dartmouth freshmen, in order that men bringing amebiasis to the college community might be discovered and treated, protecting them and their classmates from the infection. I had hoped to lay before you today the results of that survey complete. Making, as we did, a permanent slide for direct microscopic examination from each of two specimens from each student, the work of the survey thus entails the examination of some fourteen hundred slides. To date, I have finished half of them. The figures which I am about to show you are those of infections found in that part of the survey

now completed, plus a certain number found in the rest of the class while destaining slides

In this work we have had the complete cooperation of Dr Howard Kingsford, the Medical Director of the College, and Dr Harry French, who has treated all carriers. Without their help, the survey would have been useless from a practical viewpoint and impossible of completion. I also wish to acknowledge about one thousand hours of technical assistance from students made possible by federal aid under the FERA.

Following are the preliminary results of our survey

CONCLUSIONS

In addition to its practical aspects, the finding of infections among students, the purpose of our survey is to show the value of routine fecal examinations in hospitals and other institutions, and to reiterate, what we all know, that amebiasis is not limited to the Tropics, and that carriers of amebae sit among us in this room.

In spite of articles in our journals, the detection of amebic infection remains the province of trained microscopists. The average physician has neither the time for the constant practice nor the equipment necessary to make accurate fecal examinations in an economical fashion.

DISCUSSION

PRESIDENT LORD I wish to thank Dr Connell for his fine paper. I will now call upon Dr Norman W. Crisp of Nashua to discuss this paper.

DR NORMAN W. CRISP *Mr President, Ladies and Gentlemen*—There is no question but that this paper represents much work. Just the fact of his mention of 1400 (?) stools is enough to scare most anybody.

There have been papers in the literature for years concerning the occurrence of amebic dysentery in the north temperate zones, but it is only since the recent Chicago epidemic that the doctors have been active. If statistics are right as to the incidence of the disease in the United States of five

to ten per cent, there is more potential danger than we have figured.

Diarrhea and the symptoms described by Dr Connell should cause us to search for the parasite, for the diagnosis rests upon the identification of that parasite. Unfortunately, only a relatively few people are competent to identify the *Endameba histolytica*.

In the south, proctoscopic examination and recovery of the ameba from the base of the ulcer constitute the routine procedure of choice over stool examinations. The punched out, discrete ulcers, especially at the valve margins, are pretty suggestive of amebic ulcerations.

The mucosa between the ulcers is normal. Such is not the case in that loathsome disease, chronic ulcerative colitis, caused by the diplococcus of Bar gen.

Amebic colitis does not give diagnostic roentgen characteristics. X-ray will however, rule on the presence or absence of other types of colitis and carcinoma.

There is a satisfactory complement fixation test (Craig), but the antigen is too hard to prepare to permit of practical use. When such a test becomes practical, our problem in diagnosis will be easier.

The response of this disease to treatment is usually rapid and fairly good. Surgical drainage of liver abscesses is infrequently necessary. The universal treatment is, of course, emetine and arsenic.

The importance of differential diagnosis, from acute conditions in the abdomen, hardly needs to be mentioned. Yet in a recent epidemic, all the fatal cases of amebic dysentery had been operated upon. This disease is another straw for us to carry in our thoughts.

PRESIDENT LORD I will call upon Dr Harry T. French of Hanover to continue this discussion on Dr Connell's paper.

DR HARRY T. FRENCH *Mr President, Ladies and Gentlemen*—This survey of Dr Connell's is very timely, in view of the Chicago epidemic of 1933, in which something like eight hundred cases of amebic dysentery developed, with seventy deaths reported from those cases.

There are probably at least six cases that show no symptoms to one that does, it means that the number of cases from the Chicago infection is probably several thousand rather than eight hundred.

The survey of the United States, as Dr Crisp and Dr Connell pointed out, shows an incidence of anywhere from five to ten per cent of amebic carriers. And these carriers pass cysts that are thick walled and very resistant to any method of killing. They are resistant to heat and to practically all of the chemical disinfectants and they will live for long periods where conditions are favorable.

In the Chicago epidemic, we know that the spread was probably due to a water borne infection, due to contamination and with that the contamination of the food supplies. It is possible that it was also spread through the food handlers, as a survey showed several hundred of the food carriers in Chicago were infected with the disease.

As Dr Connell has pointed out, there is a danger in the spread of this disease, and the contagion comes not from the acute dysentery cases, as practically no cases will result from these people, but from carriers.

The treatment that we used in connection with the carriers we found in the college group was carbazone given in 0.25 Gm doses twice a day, with intramuscular injections of one-half gram of emetine twice daily until ten grains had been given. This treatment produced stools that were free from the cysts and amebae, and have continued to remain free in further tests.

There is one danger that I think should be spoken of in connection with the use of emetine. It is apt in overdoses to produce peripheral neuritis and involvement of the heart muscles leading to fatalities.

Another thing in connection with emetine in acute cases is that not a sufficient amount of it will be given to clear the case entirely and the infection may become resistant to the action of emetine. It is not a good drug on which to rely in the treatment of carriers for this reason.

MISCELLANY

PERSONALS

Dr and Mrs Clifton S. Abbott arrived in New York July 18 after a trip of several weeks in Europe. During their trip they visited Lisbon, Gibraltar, Algiers, Palermo, Naples, Rome, Venice and climbed the Jungfrau in Switzerland before going on to Lacerne and Paris.

Dr Robert J. Graves of Concord was elected President of the New Hampshire Surgical Club at the thirty-eighth annual convention held at the Sunnyside Hotel, Rye Beach, September 7.

Dr and Mrs. Wallace H. Tarbell of Contoocook have recently returned from a two week vacation on Cape Cod.

Dr Clarence E. Butterfield of Concord is convalescing from a recent operation.

Dr Charles W. Adams of Franklin was recently elected Chairman of the Central New Hampshire Savings Bank Association. This election automatically makes him Vice President of the New Hampshire Savings Bank Association.

HOSPITALS

The annual drive for the benefit of the Memorial Hospital in Conway was held August 15 to 18 inclusive.

Nearly 400 persons including several from Massachusetts, Maine, and other New England states were conducted August 8 on an inspection tour of the Laconia Hospital, the Nurses Home and the "Cottage" purchased by the hospital two years ago and within recent months entirely renovated for use as an annex to the Nurses home. Dr Melba Stewart Perley, roentgenologist and pathologist at the Laconia Hospital, took the visitors through the laboratory, x-ray and treatment rooms.

MEETINGS

Members of the State Board of Welfare and Relief met with physicians of Belknap County Wednesday July 18. Representative Allan M. Wilson, Chairman of the Board, discussed with the members the subject of medical charges in the county.

The annual meeting of the New England Surgical Society was held at Manchester on Friday September 27 and Saturday September 28. Operative clinics took place at the Elliott Hospital and scientific papers were given in the ballroom of the Hotel Carpenter which served as headquarters during the meeting. The annual dinner was held on Friday evening at the Manchester Country Club.

NURSES

The quarterly meeting of the New Hampshire Graduate Nurses Association was held at the Elliot Community Hospital, Keene, N. H. September 11. Dr. Hugh Galbraith of the New Hampshire State Hospital spoke before the League of Education section on "Mental Hygiene from the Viewpoint of the Nurse." Mr. James Hamilton, Superintendent of the Mary Hitchcock Hospital in Hanover addressed the general session on Group Hospitalization.

CLINICS

A Committee has been formed to start a Birth Control Clinic which will be called Concord Maternal Health Center. It was hoped that this would be started about the first of October. The purpose of this clinic is to assist those financially unable to have private physicians. Dr. Ursula Sanders is President. The other doctors serving with her are Robert O. Blood, Warren Butterfield, Carl H. Dahlgren, Thomas M. Dudley, Donald G. McIvor and James W. Jameson.

RECENT DEATHS

SPEAR—FRANKLIN E. SPEAR, M.D., practicing physician in Woodsville, N.H., for twenty-one years died after a short illness on September 5, 1935.

Dr. Spear was born July 18, 1873 in Charlotte, Vermont. He attended the academy at Shelburne, Vt., and then the University of Southern California. He secured his medical degree at the University of Vermont and did postgraduate work at the Mayo Clinic. He first practiced in Lisbon, N.H., and then moved to Woodsville where he enjoyed an extensive practice until the time of his death.

On June 27, 1907, Dr. Spear married Maude Wilmet Gibson, who survives him together with two sons, Franklin E., of Washington, D.C. and Edgar G. of Woodsville. He is also survived by five brothers.

Dr. Spear was a member of the American Medical Association, New Hampshire and Grafton County Medical Societies and the New Hampshire Surgeons Association. He was also a member of the Congregational Church and of the American Legion. During the World War he volunteered for service and was appointed first lieutenant in the Medical Corps, September 13, 1918. On November 9 he entered service at Camp Greenleaf, Fort Oglethorpe, Ga., with Co. 12, 3rd Battery and received his discharge December 21, 1918.

GARLAND—WILLIAM R. GARLAND, M.D., one of the leading physicians and surgeons of that section died at his home in Plymouth, N.H., on June 5, 1935 after a long illness.

Dr. Garland was born on March 22, 1865 in son of George W. and Eliza (Batchelder) Garland at Thornton, N.H. He received his early education

in the public and high schools of Plymouth and Holderness, later attending the New Hampton Institute and graduating from that school in 1883. He then attended Dartmouth Medical School, graduating in 1885. He took postgraduate courses at Boston and San Francisco.

He began his practice in Lancaster, remaining there but a short time. He then removed to Camp ton where he remained until 1895. At that time he went to Plymouth, opened a new office and began building up what proved to be a successful practice.

He served as medical referee for Grafton County for a time and was president of the Plymouth Hospital Association.

He held membership in the American Medical Association, New Hampshire Medical Society, Grafton County Medical Society, Eastern Society of Anesthesia of New Hampshire, International Anesthesia Research Society and was a contributing member of Current Research in Anesthesia and Analgesia.

Besides his widow, he is survived by a daughter, Mrs. Maurice Morrill, of Bristol.

NEW HAMPSHIRE SURGICAL CLUB

CARCINOMA OF THE BREAST IN NEW HAMPSHIRE*

A Preliminary Report

BY JOSEPH C. DONCHESS, M.D.†

MALIGNANT breast tumors have received an increasing amount of attention in recent years. Great progress has been made in the stimulation of propaganda to the laity for the purpose of bringing early lesions to the foreground. However, since extensive tumor masses of the breast with metastases still come into our hospitals, one may frankly conclude that our education of the laymen and even of some physicians is still far from efficient. MacCarty¹ states that carcinoma is certainly not being diagnosed early despite the repeated pleas of surgeons and the campaigns of various medical associations. Any work, therefore, however small, that is done to inform and to safeguard the patient adds to the impetus which may eventually decrease the death rate toll in carcinoma of the breast. That this painstaking effort on the part of many authors can and should show good results is borne out in the fact that early, small lesions without metastasis give 96 per cent cure when these tumors are completely removed surgically.²

The rôle of the pathologist goes hand in hand with that of the surgeon. Some lesions even when grossly exposed may look perfectly harmless, while under the microscope they may have potentialities of a highly malignant tumor. It is not uncommon to find a small mass in the breast which may show extensive metastasis. Consequently one may conclude that no tumor, however small, should be disregarded by the physician or surgeon without excision and biopsy.

In this report, which includes all breast tu-

mors sent to the Pathological Laboratory at Hanover from 1898 until July 1934, there were 1728 specimens of which 810 were malignant and 918 benign. Each slide available was carefully examined under the microscope. It was remarkable to note the preservation of the cellular structure and color stain of slides nearly thirty-seven years old. Perhaps, at this time, it would be well to honor and give credit to Dr. H. N. Kingsford whose diligent work made this report possible. Breast tumors were sent in from many towns throughout the State of New Hampshire. Data concerning each individual case were incomplete in many instances and for this reason the present report includes only those data presented in the three tables to which we shall refer later.

An attempt was made to divide the cases of carcinoma of the breast into three groups in accordance with their histological structure regarding differentiation, namely, carcinoma simplex, adenocarcinoma and colloid carcinoma (see table 1). Tumors which showed the presence of solid masses or cords of cells without the presence of definite glandular formation are classified as carcinoma simplex. In this group were included all gradations between scirrhus and medullary types. Scirrhus and medullary carcinoma, as reported in the literature, occur in about equal proportions. No definite dissimilarity has been established between the two types concerning metastasis or prognosis, except at extremes of classification. Some investigators believe a soft cellular mass recognized as medullary tumor is potentially more malignant than one of more firmness and fibrosis. Greenough³ and Haagensen⁴ have shown that fibrosis, lym- phatization and lymphocytic infiltration have no relation to prognosis in breast carcinoma. Many discrepancies by various men have arisen from

†Donchess, Joseph C.—For record and address of author see "This Week's Issue" page 775.

the fact that very often a specimen may well be placed in the medullary or the scirrhous group depending on the observers' viewpoint. Grossly carcinoma simplex may be a small or large lesion, it may be freely movable or adherent to the skin or thoracic cage. Not uncommonly there may be bleeding of the nipple and in some cases retraction of the nipple with or without

and ducts while ten cases were purely ductal in type. The average age of the acini duct type was found to be 54.2 years and for the ductal type 58.2 years. The youngest age for both types was thirty-six years.

The average duration of the tumor mass before operation for the first group was 9.25 months and for the ductal type 7.7 months.

TABLE 1
MALIGNANT TUMORS OF THE BREAST

Cases	Num ber of Cases	Aver age Age (Yrs)	Old Age (Yrs)	Young est Age (Yrs)	Average Duration of Tumor (Mos.)	Duration of Tumor Mass (5 Yrs or More Not Included in Average Duration)

Angiosarcoma	1	10 Mos.			2.5 Wks				
Lymphoblastoma	1	51 Yrs.			1 Mo				
Hemangio-endothelioma	1	7 Mos. (Male)							

ulceration of the skin. On section either glandular or fibrous tissue predominates. Almost always foci of degenerative necrosis are noted. Metastasis may occur very early or late. Lesions in the upper inner sector of the breast may involve the supraclavicular and mediastinal glands before they involve the axillary lymph nodes, in which case expectancy of cure is hopeless. Shields Warren and Witham² have shown that metastasis occurs twice as frequently in the distant as it does in the regional nodes.

The diagnosis of carcinoma simplex was made in 766 cases, 746 of which involved both acini

and ducts while ten cases were purely ductal in type. The average age of the acini duct type was found to be 54.2 years and for the ductal type 58.2 years. The youngest age for both types was thirty-six years.

The average duration of the tumor mass before operation for the first group was 9.25 months and for the ductal type 7.7 months. In the next group that more highly differentiated than carcinoma simplex, were placed the adenocarcinomas, which showed at least one-fourth of new growth with definite alveolar or glandular arrangement. There is a variable amount of stroma found in adenocarcinoma. Grossly, this tumor may not be unlike carcinoma simplex, but on section adenocarcinoma usually appears more cellular. Metastasis is

later than that of carcinoma simplex, thereby indicating a better prognosis. The secondary glandular involvement in this tumor frequently shows an absence of alveolar arrangement.

Only twenty-five of our cases were classified as adenocarcinoma. The average age was 54.7 years, the youngest was twenty-four years of age. The average duration of the tumor mass was 9.3 months.

In the third group were placed the highly differentiated group of colloid or gelatinous carcinoma, which is recognized by the secretion of a great amount of mucinous material. Grossly the local lesions usually large and on section shows a variable amount of clear jelly-like material. Metastasis is usually late, the prognosis being much better than in either of the first two groups. This tumor occurs in a small percentage of all cases. Lee, Hauser and Pack⁶ found colloid carcinoma occurs in about 1 per cent to 2 per cent of all carcinomas of the breast.

In this series three cases or 0.3 per cent of all malignant tumors were classified as colloid carcinoma. The average age was fifty-eight years and the average duration of the tumor mass was 26.3 months.

In addition to these groups there were twenty-six cases that could not be classified (see table 1), these included (1) malignant papillary cystadenoma, twelve cases, (2) fibrosarcoma, five cases, (3) Paget's disease, three cases, (4) basal cell carcinoma, one case, (5) epidermoid carcinoma of nipple, one case, (6) epidermoid carcinoma of sweat gland type, one case, (7) angiosarcoma, one case, (8) lymphoblastoma, one case, and (9) hemangio-endothelioma one case.

No attempt was made in this study to grade these malignant breast tumors. Hansemann's⁷ conception of anaplasia expressed in 1902 instituted the modern trend of grading tumors according to their degree of malignancy. Broders⁸ was one of the first to attempt a system of grading. Greenough⁹ and more recently Haagensen⁴ have made extensive studies in an attempt to grade tumors of the breast in accordance with prognosis. The grades of low, medium and high were selected. Their statements and reports show that there are so many sources of possible inaccuracies that at best, any system of grading of breast tumors by the degree of anaplasia is roughly an approximation and is of no practical value in determining prognosis. Plaut⁹, Reimann¹⁰ and Shields Warren^{11a} are of the opinion that histologic characteristics of the breast carcinoma are of little or no prognostic significance. Some observers believe that whenever a breast tumor shows a large number of abnormal mitotic figures, metastasis is more rapid and the prognosis very poor. In general, the less differentiated carcinoma simplex is more grave than adenocarcinoma or colloid carcinoma.

The number of right breasts is equal to the number of left breasts involved. That frequency of malignancy is more apparent in females whose breasts have never been nursed is evident in a report of Daland¹¹ who found seventy-one out of eighty-three carcinomas occurring in "unused breasts." Incidentally, the American Indian¹² shows no trace of carcinoma of the breast.

Radical surgical excision offers the treatment of choice of breast carcinoma. "Conservative" operations, such as simple radical amputation, on early cases yield better results than extensive operation on well-advanced cases. Five year cures with lymph node involvement average about 26 per cent to 46 per cent with different observers, while five year cures without lymph node involvement average about 71 per cent. Harrington and Judd¹³ report 55 per cent of their cases without node involvement living ten years after operation. Some authors report twenty or more year cures. We have one patient living twenty years after operation. Different authors report 40 per cent to 80 per cent lymph node involvement at time of operation. Involved nodes may not always be palpable through the axilla, and likewise enlarged nodes do not always indicate metastasis.

Prognosis of carcinoma in the young is about the same as in those of the middle age^{14, 15}. Average life expectancy of untreated cases is three years.

Every breast tumor, however benign it may seem to the examiner, should be regarded as malignant until proved otherwise.

In this group there were 918 benign lesions or 53.2 per cent (see tables 2 and 3), which only slightly exceeded the malignant tumors which was 46.8 per cent. These were divided into four major groups: (1) fibro-epithelial tumors 266 cases, (2) hyperplasia and fibrosis 367 cases, (3) chronic inflammation 271 cases, and (4) non-indigenous tumors 4 cases.

Benign tumors not uncommonly develop malignant traits. Not infrequently one sees transition of fibro-adenoma to malignant fibrosarcoma, also, intraductal papilloma are believed to develop into malignant papillary cystadenoma. Tietze¹⁶ and J. C. Warren¹⁷ believe that carcinoma develops in 10 per cent of cystic disease of the breast. Dietrich¹⁸ found 233 cases of cystic fibrosis in 500 cases of cancer of the breast.

In this series of tumors were included twelve cases of male breast tumors ten of which were benign and two malignant. The latter included one case of carcinoma simplex and one case of hemangio-endothelioma in an eleven months' old child. The remaining lesions were all of the female mammary gland.

SUMMARY AND CONCLUSION

1. A study of a group of breast tumors occurring over the past twenty-six years in the State of New Hampshire was made. One thou

CONTINUED REEDUCATION OF THE
PHYSICIAN

From time to time legislative measures have been proposed requiring periodic examinations of practicing physicians and surgeons, the purpose being to determine by some form of qualifying procedure whether the practitioner had kept apace with the continued progress of medical knowledge That such a requirement would be difficult of operation is obvious, as it would entail the establishment of special examining boards capable in each instance of properly fulfilling the functions of such qualification

It is therefore fortunate that the medical profession has assumed as its obligation the continued postgraduate education of the physician The organization of medical societies and the spread of medical journalism have been important factors in this process of reeducation With increasing facilities of transportation, graduate courses have been de-

veloped at nearby medical schools and, through the medium of extension courses, postgraduate instruction has been made available for practicing physicians without seriously interfering with their regular practice

It is to be hoped that the tendency toward specialization in the future will be confined to physicians who conform to such preparation and qualification as will justify their certification as specialists The real need of this day is the properly trained family doctor who shall be able to care for the 85 per cent of ail illness that does not require the services of the specialist in a limited field For the family doctor of the twentieth century the refresher courses that are arranged convenient to his territory will have a special appeal The real attraction of a medical career at all times has been the urge and opportunity for continued study, and it is this quality that truly exemplifies the ideal practitioner of medicine—*Federation Bulletin*, September 1935

EVOLUTION OR REVOLUTION*

BY ROY J. WARD, M.D.†

ONE hundred and forty years ago next month Dr Bahntt gave the first of the annual orations before this Society. Since that time many distinguished men have appeared as orators and it is with considerable trepidation that I attempt to occupy a rôle with such company. The subjects, which have been discussed during these one hundred and forty years, have varied much. Many of them were about the social relations of the physician to the community. Some were epoch-making in meeting the medical problems of the day, others have been historical in nature and, had they been preserved, would have been a veritable mine of information for the future historian of Worcester County medicine.

Since the appearance of the report of the Committee on the Costs of Medical Care there has been the most acrimonious debate, on a purely professional problem, which has been noted for many a generation. In fact the physician, in his relationship to social welfare, has been, so to speak, "pnt on the spot."

Many plans have been suggested to give adequate medical care to all classes of people. The methods which have been in vogue in Germany since 1883 and in Great Britain since the war have been studied carefully. Congress is considering, at the present time, a bill to provide federal subsidies to the states for maternal welfare, child welfare, and sickness insurance. Many of the states have similar bills before their legislatures.

The Bureau of Medical Economics of the American Medical Association, the Julius Rosenwald Fund of Chicago, the Milbank Memorial Fund of New York and the newly established Department of Medical Economics of the Harvard Medical School are all studying the problem which these Congressional and State bills propose to solve.

Many medical societies in Texas, California and Michigan have plans, actually in use whereby the profession controls forms of health insurance and the payment of medical costs. They have elaborate organizations for studying the social need and responsibilities of the individuals in the low income groups and their ability to pay part or all of the costs. These plans have been advanced to forestall the entrance of politics into a purely professional problem.

Dr Ernest L. Hunt has called to my attention a new method of financing the expense of sickness which I have never before seen sug-

gested. The plan is to have savings banks or organize Health Clubs patterned after Christmas Clubs. Such clubs would obviate many of the objections which are inherent in compulsory health insurance. Some control over funds raised for this purpose should be maintained by the bank in order that they should not be dissipated for luxuries. As an inducement hospitals and physicians should offer a discount to those who may pay from such funds. Under such a plan the individual has no chance of losing and has everything to gain. This plan would tend to even up the unequal distribution of money between the luxuries and the necessities of life.

One of our members, Dr Gilbert Haigh, has worked out a plan which has been submitted to several legislatures. He proposed putting the entire profession in all of its branches under state control but this plan was so all inclusive that it gained few supporters. He antedated by several years that which may be forced upon us.

With these few exceptions, however, most of the activities of organized medicine have been directed in opposition to any and all plans which have been brought before Congress and many of the State Legislatures. In some instances general policies have been suggested. This attitude of organized medicine has not been constructive and often it has been destructive. The *New England Journal of Medicine* recently said, "The medical profession can supplement and guide—it cannot ignore—public opinion." Antagonism will only bring our profession to the point where the British physicians were when Lloyd George forced upon them a plan for socialized medicine. It was only after a hard battle that any modification of that act was obtained. William Hard, journalist, of Washington says, "Legislation for government compulsory health insurance is inevitable in Washington." He sends this word, "My dear doctors, those of you who are not converted to the idea, remember that when a thing is inevitable in Washington it is smart to jump in and swim along with the current and you may be able to help it along your way a bit."

The history of the growth of state medicine shows that it has been put forward as a stop-gap to an oncoming revolution. Bismarck, in Germany, first suggested this method of appeasing a rapidly growing dissatisfaction with social conditions among the poorer classes. The same background was present in England when Parliament crowded state medicine upon the profession. Evidently this is one of the reasons that Washington is now forcing this subject to the front, i.e., to forestall social unrest.

*The annual oration delivered at the Annual Meeting of the Worcester District Medical Society May 8, 1935.

†Ward, Roy J.—Visiting Physician, Worcester City Hospital. For record and address of author see "This Week's Issue," page 774.

Many of us who have watched the development of and the increasing interest in some form of state medicine feel that we are fast approaching the time when the entire background of the practice of our profession is to change. It behooves us to develop some concrete program of our own before a political program is forced upon us. The first step in such a plan is to develop a community of interest among the members of this society and I trust that the suggestions advanced before us last December by Dr William Lynch will bear fruit. The Worcester District Medical Library, Inc., with new quarters in Town House will be of great help in this. I anticipate that the younger members will show the community that the study of medicine costs the most in time and money of any of the professions and, in the words of Dr Channing Frothingham of Boston, "while good medical service is expensive, poor medical service at any price is more expensive."

Most of the plans for meeting the cost of medical care which have so far been suggested by medical societies have some form of contributory sickness insurance in them and concern only people of the low income groups. Very little attention has been given to the group with no income, i.e., the indigent.

I am going to devote the remainder of my paper to a discussion of the problem of providing adequate medical care for the group of people with no income. I feel that this problem should be solved, by experimenting first with the no income group. Then after a successful plan has been evolved, I should like to see it carried along to the low income groups.

Among the many booklets and pamphlets sent to me by the Bureau of Medical Economics of the American Medical Association was a sheet which gave the majority report of the Committee on the Costs of Medical Care, the minority report of the same committee, the attitude of the Committee on Medical Education, and the editorial opinions of the *Journal of the American Medical Association*. These differed in all phases except one. All agreed that medical relief to the indigent should be provided from public funds. With this consensus probably most of us agree. Let us now discuss how far we have already gone on the road to state medicine.

In 1878 Dr Rufus Woodward was appointed to the newly created Board of Health in Worcester. The first report of the board dealt with complaints about sources of filth, the keeping of swine within the city limits and the supervision of the cleaning of privies. Dr Woodward declared that drainage running from sinks into the gutters on Main Street should no longer be tolerated.

Thus some fifty-five years ago, state medicine had its beginning in Worcester and for the first time our city government began to take a paternal

interest in the health of the citizens. Evidently Dr J Kelley had prophetic vision some fifty-four years ago, since he took for the subject of his annual oration "State and Preventive Medicine." If time allowed I should like to trace in detail the gradual increase in the activities of the Board of Health from the time of privy inspection to the present, and how the state and local health authorities have taken on step by step added functions in caring for the health of our citizens.

Let me briefly enumerate some of the epoch making advances which began with compulsory reporting of contagious diseases and the quarantine of that dread disease, smallpox. Our Dr Frederick Baker was instrumental in establishing the first municipal laboratory in New England for the bacteriological examination of sputa and diphtheria cultures. Following his oration, which he gave twenty years ago, on "The Relation of Venereal Disease to Public Health" a great impetus was given to the control of gonorrhea and syphilis by the diagnostic aids which were added to his laboratory services.

Soon after the discovery of diphtheria antitoxin, and, while it was still out of the reach of the ordinary patient because of its cost, the state came forward to furnish this expensive therapeutic aid to all. The need for a hospital for contagious diseases was soon seen and Belmont Hospital was established, where, at the present time, a large per cent of the patients are cared for by the city free of charge. A large group of employees have been added to the Health Department such as sanitary inspectors, milk inspectors, school physicians, epidemiologists, school nurses and dentists. The City Health Department, in conjunction with the State Health Department, furnishes consultation services to general practitioners for tuberculosis, infantile paralysis and cancer and supplies a large number of biological and pharmaceutical products. Charitable and volunteer organizations are antedating the public health programs and are carrying on many health projects. Some of these have paid staffs, such as the Medical Milk Commission of Worcester, the District Nursing Association, the Tuberculosis Association and Cancer Follow-Up Clinics. Probably many of these activities will be taken over by the Health Department when they have proved their value.

I wish to pay a tribute to the late Dr Thomas Kenney, former director of public health in Worcester, who had a vision of the needs and possibilities of health work which was far beyond his strength to carry out. He saw the importance of the public health nurse as the liaison between medical science and the mother in the home. He raised the work of public health in Worcester to a high level and by his personality obtained a better recognition of the monetary value of a trained health worker.

The City Hospital is also engaged in state medicine in that it furnishes hospital service to a large group of patients 66 per cent of whom pay nothing to either the hospital or their physicians. The City Hospital Out Patient Department has been overwhelmed all through these years of depression with the volume of service which has been thrust upon a willing but overworked staff whose services are even gratuitously to the city. People on welfare who apply to other hospitals are immediately sent to join the crowd at the City Hospital. The Welfare Department employs three physicians who can only make the most perfunctory examinations because of the many patients they are asked to see. They either send the patient to the hospital or give them a bottle of medicine.

I have tried to sketch the growth and development of the public interest in the health of the community and how the City and State has gradually broadened its scope of work to include not only preventive but also curative medicine. I have listed some of the functions of the voluntary organizations which are pointing the way and demonstrating the value of further activity along public health lines. I have tried to bring to your attention how free public clinics are being overwhelmed with work they cannot do satisfactorily and how physicians for the Welfare Department under the direction of social workers are operating under great hardships with results which are not satisfactory to any one.

As mentioned before all of the plans advocated by social workers, politicians and even medical societies which would provide adequate medical care to the various groups in our communities, have failed to give proper attention to the needs of the indigent. In spite of all that the State, the City and private charity are doing the medical dental and nursing professions have to give the major part of the service with out remuneration.

The New Deal has spent millions of dollars for the relief of this indigent group yet little of it has reached the medical profession. In many of the states the ERA has furnished medical services to their workers and their families. Dr Hunt tells me that in Massachusetts the money allocated by the Federal Government for medical care has, through some maneuvering been used by the local communities to reduce the tax rate leaving all the burden on the shoulders of the profession. Unemployment faces the doctors as well as other white collar classes. In a recent questionnaire it was disclosed that forty-eight of our profession stated that they knew physicians who were on the welfare. Unemployment insurance or health insurance will never solve this problem.

Medical relief to the indigent has as much monetary value as any other form of relief for which the millions are being poured out. Provision should be made for it in every budget

which is made up. In approaching a plan to give medical relief to the indigent we must avoid, if possible the errors and pitfalls which have developed in other countries. If we do too much for these irresponsible individuals we shall take away from them the will to get well and to a certain extent, we shall be defeating our own ends. Some stimulus must be given which will aid in creating an ambition to rise out of that class if possible. The major problem of malingering has always been, and always will be with us and some way to lessen this evil must be found.

There is some difference of opinion concerning the question of the administration of a public medical service. Should it be by a department of social welfare or by a department of health? Dr Thomas Parran, Jr., Commissioner of Health in New York says "I hold very strongly to the view that all public medical and health work should be done by the health department. Here we have the medical backbone which is lacking in social workers. Counterbalancing this however the social workers make out a good case for unifying medical relief with other relief and social reconstruction measures. This argument, plus the continual harassment of some medical groups to make prevention and not cure the objective of health service may reduce health departments to the status of sanitary police while the major health promoting functions of the community are carried on by non medical agencies."

Most of us will agree that the medical problems in all branches should be under medical control and we must also agree that our health departments, by a gradual process of evolution have changed from purely preventive medicine to curative medicine in several particulars. They have skeleton organizations, already functioning, which can be enlarged to care for the indigent. It has been said that 80 per cent of the troubles which need medical care can be handled by the regular practitioner with the equipment which he has with him. This being approximately correct with an enlarged personnel the health department could care for much of the work that now crowds our out patient departments and could at the same time care for at home many of the cases which now occupy valuable hospital beds. The accessories to good medical service such as the x ray the laboratory and nursing services, which because of the large extra cost, are prohibitive to many can be furnished by the state with some enlargement of the service which they already supply. In fact it is for laboratory and x ray studies that a large number of patients are sent into hospitals to occupy valuable beds.

The next question to arise is "How shall this enlarged personnel be recruited and how shall they be paid?" In New Hampshire the County Commissioners who have the care of the indigent refer cases to local physicians and pay

them on a fee basis of two-thirds of the regular rates. Dr Robert J Carpenter has written to me that in North Adams they are operating on the plan that all people who are on the welfare are eligible to receive medical care from their former physicians. The physicians send bills to the city at regular rates for office and house calls, the city takes fifty per cent off the bill and pays the rest.

I suggest that for the people who are only temporarily on the welfare the North Adams or New Hampshire method be adopted and that those people be taken care of by their former physicians because we all know that individual attention by a skilled and interested doctor is the best type of medical care. Those who are regular recipients of welfare aid should be referred to recent graduates of our hospital internships who have obtained membership in this society. I hear some one ask, "Why limit such service to members of this society?" Membership in this society should be a yardstick of medical competency and this society has the best plan to maintain this competency through post-graduate courses and medical meetings. Few of us can maintain our hold on our rapidly advancing science without faithful attendance upon the proceedings of this society and the perusal of current literature. We must make membership in this society an honor and a privilege.

The amount of work which any one on the health department panel should do ought to be limited to that which he can satisfactorily carry out. Or better still, the work should be evenly

distributed among those in the first years of their practice. With the aid of the municipal laboratories these men should be able to care for many of the cases that are now sent into the hospitals. This would liberate valuable hospital service for diagnostic, surgical, and maternity cases. Provision should be made for research work. Under competent supervision these recent graduates can make this large amount of clinical material contribute to medical knowledge.

I have already pointed out that it would not be wise to make the lot of the recipient of state or city medical relief too attractive because of the liability of the loss of ambition to improve one's condition. It is an injustice to have all patients in our hospital wards getting the same care when only one out of three pays for the service rendered. It puts a premium on the lazy man and it is discouraging to the one who provides for the rainy day.

I visualize, in the future, physicians' offices grouped around our hospitals, state or municipal laboratories where all the essential accessories to good medical service will be supplied by the state. Our hospitals will be largely reserved for diagnostic problems, maternity service and surgery. Physicians will receive compensation for medical relief rendered to the indigent and, with a large part of the overhead cost of medical service furnished by the state and the physician freed from his burden of caring for the poor, the expense to the average citizen will be materially reduced.

THE ADULT TUBERCULOSIS CONTACT*

BY HERBERT R. EDWARDS, M D †

THE examination of the adult tuberculosis contact is an old theme. It has been allowed to drift into the background for the important, but far less productive child contact. Tuberculosis workers are prone to seek the dramatic, large scale project that gives numbers, but proportionately fewer cases. Our responsibility as investigators and workers in this field demands that we tackle the job at the sorest point, and until we have made reasonable strides in that direction, I doubt that we are justified in placing all of our emphasis on the easier and more intriguing routes.

Our greatest problem in any sound program of control always has been, and will continue to be, the adult contact. There is abundant evidence to corroborate this statement in a perusal

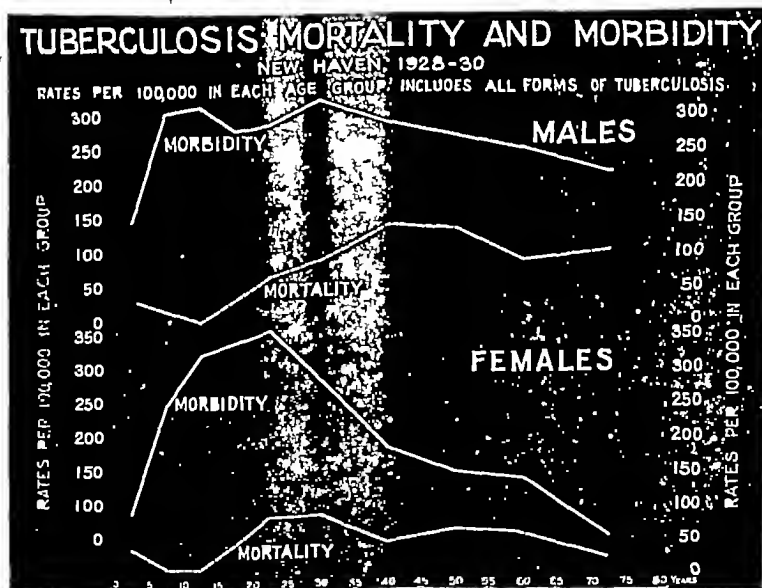

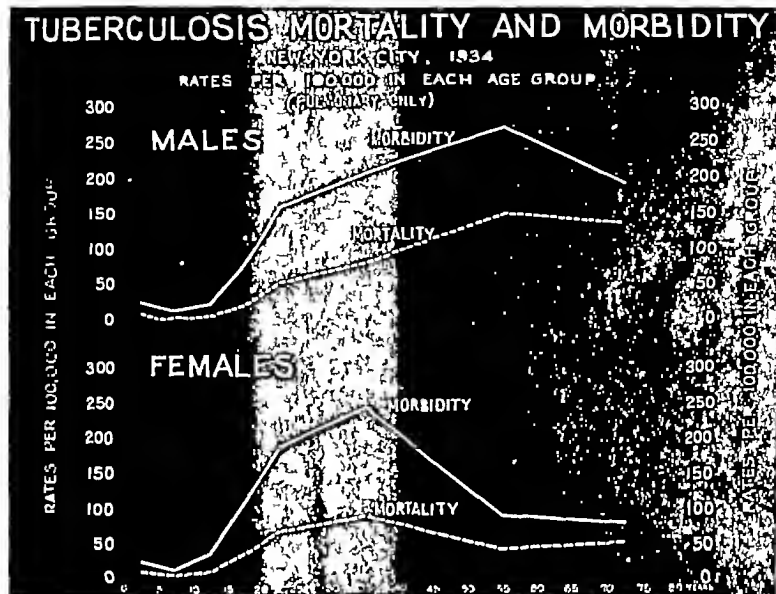

of our morbidity and mortality statistical data. Our new cases are reported chiefly among individuals above fifteen years of age, and our mortality data show clearly that the problem of death from tuberculosis is chiefly one of the adult groups. The problem becomes sharply acute among females between fifteen and thirty-five years, and among males between forty and sixty years.

Pulmonary tuberculosis is the most characteristic form of the disease among adults, and it is this type of the disease that accounts for the major portion of infections. The seriousness of the bacillary case is well known, and of particular importance is the case untreated at the time of death.

Contact examination regardless of age is a difficult problem and one for which we have not as yet found a reasonably satisfactory solution. In selected families, 100 per cent cooperation is possible, but in the average community the contact problem is usually less than half solved,

*Read at the Annual Conference of the Advisory Council Milbank Memorial Fund New York Academy of Medicine March 27 1935

†Edwards Herbert R.—Director Bureau of Tuberculosis New York City Department of Health 1934.—For record and address of author see "This Week's Issue" page 775

and the greatest percentage of unexamined are invariably found among adults. In New Haven, after the most intense efforts had been made to clear contacts, we found that in only 31.1 per cent of 1428 families registered as presenting a tuberculosis problem, had we secured examinations of all household contacts.

The promptness and energy with which we approach the family following the discovery of the primary case, do not appear to solve the problem. In New Haven¹ and at the Henry Phipps Institute² a check of contact examinations within a year of the discovery of the primary case showed only about 47 per cent complete, with essentially the same amount of disease in both studies. In both places, it is reasonable to assume that every modern method of approach was utilized to secure cooperation from the contact. As a matter of fact, if we consider the cost involved, there is a serious doubt as to how far we are justified in going with present-day methods. This does not imply that we are to accept a defeatist attitude, but rather that we shall approach the problem with newer and more effective weapons.

Every tuberculosis worker has seen time and again in his experience the acute case of tuberculosis develop in a heretofore unexamined contact, and it is logical to believe that many of our family reinfections occur through similar sources. The inference is clear that had we known more about that individual in the years preceding his break, it might easily have been averted.

The problem may be visualized by a comparison of morbidity and mortality by sex and age groups (Charts 1 and 2).

Some recent studies dealing with contact examination throw direct light on the problem and the seriousness of the adult contact. Haywood et al.³ examined 604 or 96 per cent of all contacts in 156 families. The highest percentage of manifest lesions was found in the age groups fifteen to nineteen years (14.2 per cent) and in the individuals over sixty years (16.6 per cent). Males showed a persistently higher proportion of positive x-rays in all age groups except fifty to fifty-nine. When the source of infection was parental, there was found to be a greater danger to children. Of the 604 individuals examined in their study, twenty-nine or 0.48 per cent were classified as clinically active. Of these, 24.1 per cent were between fifteen to nineteen years, and 58.5 per cent twenty years or above.

Jessel⁴ reporting on the examination of contacts in Lancashire County, England, came to the following conclusions: (1) In 15 per cent of the cases accepted as cases of pulmonary tuberculosis, instances of one or more secondary cases occurred. (2) Nearly all secondary cases were directly related to those primary cases

where tubercle bacilli were found in the sputum. (3) The average interval between the discovery of the primary and secondary cases was three and a half years. (4) Relatively more attention should be paid to adults, and especially middle-aged contacts. (5) A single negative examination result may well lead to a false sense of security.

Turner⁵ reporting from North Worcestershire on tuberculosis morbidity and mortality among 833 house contacts of sputum positive cases in 185 households, concludes as follows: (1) Of 185 sputum positive cases, only one was under fifteen years, 146 between fifteen and forty-five years, and thirty-eight beyond that age. (2) There were seventeen deaths due to pulmonary tuberculosis, one under fifteen years, ten between fifteen and twenty-five years, and the remainder, or six, above twenty-five years. These occurred during a period of thirty-two months' observation. (3) During the same period, there were twenty cases of tuberculosis with positive sputum reported, all above fifteen years, thirty-two cases with negative sputum were reported, eighteen of which were above fifteen years. Sixteen cases of non-pulmonary forms were reported, chiefly under fifteen years. Of the suspicious group, twenty-eight of the forty-nine were found in contacts over fifteen years. (4) The incidence of tuberculosis among his series of contacts was 116.4 per 1,000, of which 82.8 per cent were pulmonary, this development of disease occurring in the short space of thirty-two months. (5) The modal age at death from phthisis occurs in the age groups fifteen to twenty-five among contacts and is well marked, whereas in the general population the modal age at death occurs in the twenty-five to thirty-five years age group and is not well defined.

Barclay⁶ reporting on 413 contacts of pulmonary tuberculosis in 132 families demonstrated tuberculous lesions in 21.8 per cent and active tuberculosis in 17.2 per cent, 15.5 per cent having pulmonary lesions. He states that the most fruitful field for intensive effort is among contacts of bacillary tuberculosis and those relatives exposed to a recently fatal untreated case. The incidence of tuberculosis was greatest under five years and over fifteen years. He reports 18.6 per cent of consorts as having tuberculosis, 9.8 per cent husbands and 27.5 per cent wives, which he accounts for on the basis of the wives giving more intimate care to the husbands than the reverse.

In New Haven^{7,8,9} for several years, we placed great emphasis on the examination of contacts, and our findings indicate clearly that the adult contact is by all means the most important contact for study.

In a series of 162 families in which the primary case was one of pulmonary tuberculosis, we were able to examine all contacts. Of the adults, 15.5 per cent were diagnosed as pulmo

nary tuberculosis, compared with 5.4 per cent in children. In a series of nine families in which the primary case was tuberculous meningitis, pulmonary tuberculosis was found in 38.1 per cent of adults, compared with 6.9 per cent of those under fifteen years.

An analysis of 155 children originally classified as Childhood Type Tuberculosis showed that nine or 5.8 per cent developed pulmonary tuberculosis during adolescence or early adult life. Hall and Chaug¹⁰ reporting on a similar study among the professional class of Chinese found that 4.1 per cent developed a manifest pulmonary lesion in young adult life. These studies indicate not only the adult phase but the importance of repeat examinations.

Another observation of importance to this subject in New Haven⁸ was based on an analysis of 661 families representing 3856 contacts. Two thousand, six hundred and ninety-three or 69.8 per cent were examined adults, 59.8 per cent and children 79.5 per cent. Substantially higher percentages of examinations were made in families where the primary case was pulmonary tuberculosis. Pulmonary tuberculosis was diagnosed in 28.36 per cent of the contacts, and adults accounted for 83.0 per cent. There were 323 or 42.3 per cent of those diagnosed pulmonary tuberculosis who were known to have been bacillary cases. This percentage is undoubtedly low. There were 306 deaths due to tuberculosis and 83.3 per cent occurred among adults.

The further reiteration of studies dealing with the adult contact is superfluous. It is the problem of first importance in any sound program designed to prevent and eradicate tuberculosis. The real problem confronting us is how best to develop our program.

There are certain types of families in which the problem is more acute and they should constitute our first and most intensive efforts toward case finding among adult contacts:

1. Families in which a bacillary case is discovered.
2. Families in which there has been a case or death of tuberculous meningitis, or other acute forms.
3. Families in which the primary case was discovered at death. Barclay⁶ states that 25.7 per cent of contacts to cases dying at home were found to have tuberculosis.

Families in which a non-bacillary case is discovered are important depending upon the character of the lesion. Families with a non-pulmonary form of tuberculosis are of the least importance though they cannot be entirely ignored.

The public health nurse and tuberculosis clinician are in the first line of attack. After careful study of the problem in New Haven and elsewhere the conclusion becomes obvious

that a part of our difficulty in securing cooperation from the adult contact may be traced to the first and subsequent associations of the family with the representatives of the public health agencies. The frequent changing of nurse or clinicians handling the individual family tends to weaken the position of the health authorities, and this situation is aggravated if those associations have been made by untrained and disinterested individuals. The fact must be accepted that all nurses do not and cannot approach the tuberculous individual with equal confidence, interest, and the ability to mold the attitude of the patient. There are nurses who, from personality and training are able to carry their campaign with the family through to a successful conclusion. The generalized nursing service as generally adopted at this time is based on sound economic lines, and it is not possible in many communities to change the situation yet with it we must accept a less efficient service for many of the tuberculous.

The clinician, occasionally not appreciating the sociological and economic problems involved, fails to command the interest of the patient, and that unfavorable reaction is carried into the home of the patient.

Indifference of the patient is one of the most common problems met with in contact work. It may be the result of poor handling by the nurse or clinician, or due to fear. Jessel states, "Reluctance to be examined is a suspicious feature in itself. Such persons frequently become patients sooner or later and a source of infection to others. The readiest to permit examinations are often those obviously in good health."

The question may well be raised as to the length of time the adult contact should be supervised. In New Haven, we endeavored to follow all contacts through their twenty-fifth year. This age would appear to be a minimum for both males and females, on the basis of the sharp rise in deaths during that period. The general factors determining the frequency of re-examination will depend upon the seriousness of the original infection in the home, the intimacy and duration of the contact, the general health status of the individual and the factors determining the economic conditions of the family.

It is difficult to keep the interest of the patient if re-examinations are spaced far apart. Yearly examinations should be the maximum, with preferably nine-month intervals. It will require tact on the part of the clinician to hold the interest of the patient without causing undue alarm about his condition. It is in such cases that the idea of the annual physical examination should be presented in its most tempting and alluring form.

The re-examination of the adult beyond twenty-five years could well be predicated on the above suggestions. There are undoubtedly many contacts not in need of persistent follow

up A choice must be made of those most likely to show a spread of disease, if our program is to be economically feasible Racial susceptibility and occupational hazards should be carefully considered in the selection of the group for extended care

In practically all of our case-finding work, our programs have been built around the clinic, sanatorium or practitioners, at all events, we have expected the patient to come, to us These methods permit of better diagnostic facilities, and will serve for the major part of our work There is, however, need for more intensive work in the home The undiagnosed case constitutes a major public health problem, and it would seem that if the established method is inadequate, we should go to the home to locate possible open foci of infection It does not necessarily follow that such a plan would discourage clinic attendance The contact made in the home, on the other hand, should serve to convert the patient to his responsibility in the control of tuberculosis

Turner⁵ and Jessel⁴ both secured part of their reported examinations in the homes of the patient They depended upon careful histories and physical examinations for their diagnoses On this point, Barclay⁶ states that 51.1 per cent of his contacts exhibited definite or suggestive recent symptoms, and about 40 per cent could have been diagnosed entirely on this basis In only three of his contacts did the initiative come from some member of the family or the patient himself, and only 61.1 per cent of his series were examined at the request of the sanatorium physician As efficient as these simpler methods of diagnosis may be, they do not preclude the use of a portable x-ray in the home The apparatus is available, and can be used in many homes

It is our present plan in New York City to develop a mobile clinic staff with portable x-ray facilities, to develop the possibilities latent in this newer approach.

Public health education has gone far to change the attitudes of the populace in regard to tuberculosis, but there is still a wide field that has thus far been only partially touched Such measures must reach the individuals in the

tuberculous household and help to create a more intelligent attitude toward their responsibility to their family and the community

SUMMARY

A review of certain of the recent contributions to the literature on the tuberculosis contact indicates beyond a doubt that the adult contact is the major problem in our case-finding efforts

It is not enough to examine these individuals once if found to be negative, the effort must be repeated at periodic intervals, as not infrequently a latent unrecognized disease develops into an active infectious one

The difficulties in securing cooperation from the family contact are manifold Indifference may be the result of a poor technic in the approach by the representatives of health agencies, fear on the part of the patient, and the limited horizon of the patient in his responsibility to his family and the community This may be altered through the channels of public health education

An approach to the present uncooperative contact should be made through the medium of home visiting Such a plan demands a well-trained and sympathetic staff of physicians and nurses, and portable x-ray facilities

THE CO-INCIDENCE OF CHOLECYSTITIS AND PEPTIC ULCER*

BY EDMUND G. LAIRD, M.D.†

DURING the past year attention was called to the apparent frequency with which peptic ulcers were observed coincident with gallbladder disease at the New York Hospital A great

number of writers have reported varying numbers of cases of gallbladder disease coexisting with peptic ulcer, but few have offered actual statistics For instance, MacLaren¹ (quoted from Bruce) reports five such cases, Ochsner in lectures mentioned its occurrence Baumgarten², L. B. Wilson, C. L. Mix³, B. G. A. Moynihan and a multitude of others cite small groups

*From the Surgical Department of the New York Hospital and Cornell Medical College.

†Laird Edmund G.—Assistant Resident in Surgery New York Hospital 1933-1935 For record and address of author see *This Week's Issue* page 775

of cases but gave no data concerning large series.

Wikie⁷ recognizes a clinical picture, especially common in women, in which the patient presents symptoms more suggestive of gallbladder disease but at operation is found to have duodenal ulcer. He calls this the "cholecysto-duodenal syndrome."

On reviewing the literature on this subject one becomes almost inevitably involved in the various theories of the origin of the so-called "abdominal triad", i.e., peptic ulcer, cholecystitis and appendicitis. Lichtenfeld, Talma and especially Rössle⁸ have furthered the somewhat more recent belief in the neurogenic origin of these conditions, that is to say, that they are due to visceral vascular and muscular reflexes arising from the central nervous system, especially common in the vagotonic types of individuals. Rössle, supported by Preusse, Richter, Reischauer, Schmieden, Bergmann and Westphal, familiarized the term "zweite Krankheit" for the conditions in this triad in order to emphasize the idea that they are not primary affections of the local parts but conditions secondary to disturbances of the autonomic nervous system. Hinrichsen⁹ cites a rather large group of cases in which these three conditions occurred in each patient. A diseased appendix was found by Larimore¹⁰ in all cases of associated cholecystitis and peptic ulcer. Moynihan¹¹ states that all cases of peptic ulcer and gallstones are probably "secondary" to some infection or toxemia arising in some abdominal organ, most frequently the appendix.

Lymphatic connections between the duodenum and gallbladder have been demonstrated by many observers (Sudler, Cuneo, Deaver, MacCarthy and Jackson, Graham, Judd and Peterman). Braithwaite¹² injected dye into the region of the iliocecal angle of human beings and demonstrated its flow or extension by way of the lymphatics up to the subpyloric glands on the inner side of the pylorus and into the subserous coat of the duodenum. Occasionally it could be made to pass into the subserous lymphatics along the common duct itself. This, he admits, is not the usual pathway but is favored by a chronic lymphatic infection congesting or obliterating the normal channels of lymph flow. Moynihan and Oldfield (quoted from Braithwaite) have seen examples of similar lymphatic flow in patients with tuberculous infections of this region. Braithwaite consequently adheres to the infectious or focal theory for the etiology of cholecystitis and peptic ulcers as opposed to the neurogenic, circulatory (embolic) or digestive theories.

The purpose of this paper is not to attempt to evaluate these theories but to consider briefly the available data on the subject of the frequency of concurrent gallbladder disease and peptic

ulcer, and to present the results of a study of a group of such cases.

Four patients with persistent, refractive duodenal ulcers were studied by Baumgarten¹³ at St. Luke's Hospital and were eventually found to have a coexistent cholecystitis. Cholecystectomy caused in all four patients an almost immediate disappearance of the peptic ulcers, so that the author formed the conclusion that cholecystography should be a routine part of the study of patients with peptic ulcer.

Bruce¹⁴ found five cases of duodenal ulcer, unsuspected from either the clinical symptoms or x-ray findings, in 100 consecutive gallbladder cases, plus two which were recognized before operation as coexisting.

In 1929 McVicar and Weir¹⁵ observed a case of coincidental gallbladder disease and peptic ulcer. As a result of this finding they compiled some statistics on 500 consecutive cases of gallstones and 500 consecutive cases of duodenal ulcer. Moreover they separated the sexes and found a slight difference. Their results were as follows:

Coincidence in Males		
Coexisting gallstone disease in duodenal ulcer		10.0%
Coexisting ulcer in gallstone disease		1.0%
Coincidence in Females		
Coexisting gallstone disease in duodenal ulcer		3.6%
Coexisting ulcer in gallstone disease		7.1%
Coincidence in both groups (500 ulcer cases and 500 gallstone cases)		
Males		3.9%
Females		4.3%

The coincidence in both males and females in the total series of 1000 cases was thus found to be 4.1 per cent. In conclusion they say, "In fact it is probable that the incidence of cholecystic disease in the ulcer group is not much greater than that of any comparable age group of the general population and conversely that the incidence of duodenal ulcer in patients who have cholecystic disease is not greater than the incidence in those of comparable age who have normal gallbladders."

This report is based on a study of 250 consecutive patients with gallbladder disease upon whom cholecystectomy was performed. Out of these 250 patients, twelve or 4.8 per cent of the total number were found in which cholecystitis and peptic ulcer coexisted.

Examination of these twelve patients revealed the following facts:

- 1 Ten patients showed evidence of a chronic gallbladder infection. One patient was admitted with a subacute cholecystitis and another with acute cholecystitis.
- 2 Cholelithiasis was associated with the cholecystitis in five instances.

- 3 Of the twelve patients, eleven had simple duodenal ulcers, the twelfth had one gastric ulcer and multiple duodenal ulcers
- 4 In ten the ulcers were in the first portion of the duodenum, usually on the anterior surface and near the pylorus
- 5 Gastric analyses were carried out in five of the twelve patients. Gastric acidity was normal or high in every instance
- 6 Occult blood was found in the stools in two instances and a history of tarry stools was elicited in two others
- 7 The appendix was not mentioned in five instances, previously had been removed in one, was definitely diseased in four, and was normal in two
- 8 Over varying periods of follow-up observation, eight patients recovered without further symptoms of gastric pathology, three continued to have mild symptoms of dyspepsia, one subsequently died from septicemia following a carbuncle

To return to our figure of 4.8 per cent of coexisting cholecystitis and peptic ulcer, it seemed essential to compare this with the percentage of ulcers that one would encounter in a large number of individuals selected at random. Examination of the literature disclosed abundant statistical material suitable for such a comparison. Finney and Hanrahan¹² have compiled much of the literature dealing with the occurrence of peptic ulcer in large, general series of autopsies. As reported by them, Brinton, Fenwick, von Jaksch, Leube and Welch studied 100,000 autopsy reports and found the incidence of gastric ulcers to be 4.5 per cent to 5.0 per cent. These figures, based largely on the findings in Europe, are uniformly higher than those found in more recent American reports. In 31,815 American autopsies, gastric ulcer was found in only 1.3 per cent. Bassler (1922) compiled 59,450 records showing 4.4 per cent of gastric or duodenal ulcer. In 2081 autopsy examinations, Carl Hart¹³ found 7.17 per cent of the adults (5.2 per cent of the total) showed gastric ulcers, 4.6 per cent of the adults (3.8 per cent of the total) showed duodenal ulcers. These percentages are higher than those of Gruber (2.98 per cent), Schönberg (3.16 per cent), or Nauwerck (2.4 per cent), but not so high as those of Rossle (8.3 per cent—12.4 per cent).

From a glance at the above figures it would appear that the percentage of people showing peptic ulcers is not appreciably higher among those suffering from gallbladder disease than among the general population.

A comparison of our findings (4.8 per cent) with other available data shows that they agree quite closely with those of McVicar and Weir (4.1 per cent) and less closely with those of Bruce (7 per cent). Schutz¹⁴ observations are

also in accord with ours. He claims that such a coincidence is an infrequent occurrence, as would be expected since most duodenal ulcers occur in men whereas cholelithiasis is chiefly found in women.

Kalk and Siebert¹⁵, however, believe in a closer relationship between the two conditions and, by determinations of the icteric index in a series of patients, have demonstrated that the bile passages are affected in about one third of the cases of duodenal ulcer. Gruber¹⁶ also finds a more frequent coincidence between the two conditions and states that 16 per cent of a large series of cadavers with duodenal ulcer showed cholecystitis with cholelithiasis. Lessening the significance of this finding is that of Ehrman who in 15,000 unselected autopsies performed during fifteen years, found gallstones in 16 per cent of the females and 6 per cent of the males.

A more or less incidental investigation of the 250 records studied concerned the status of the appendix. It was found that in 104 or 41.6 per cent of the patients a diseased appendix had been removed before the operation upon the gallbladder or was simultaneously removed with the gallbladder because it showed evidence at the operating table of disease. This figure is considerably higher than those commonly found in the literature.

SUMMARY

Two hundred and fifty cases of cholecystectomy are reported with special study regarding the coexistence of gastric or duodenal ulcer. Peptic ulcers were proved to exist in 4.8 per cent of the cases. A review of the literature shows comparatively few statistics on this relationship but such as may be found are in close agreement with the above figure. As determined by reported autopsy records this incidence of peptic ulcer with cholecystitis is not markedly higher than the percentage of ulcers found in the general population. Therefore no close interrelationship between the two conditions is suggested by this study. Evidence of a diseased appendix was found in approximately 41 per cent of the cases of gallbladder disease and it is probable that the relationship between appendicitis and cholecystitis is a more important one than that between ulcer and cholecystitis.

CASE 21421

PRESENTATION OF CASE

A one year old female child contracted a head cold in February, approximately one month before entry. Associated with this was a nasal discharge and slight elevation in temperature. She developed bilateral otitis media and both ears were opened and drained for a few days, following which they healed. Ten days before admission the child started to cough and her temperature again became elevated. On this day she also fell from her crib, became quite pale, but did not lose consciousness. Five days later she appeared much sicker than usual, was quite drowsy and sleepy all day. There was no vomiting. Three days before admission the cough and fever increased and her legs seemed stiff. Her eyes became glassy and her father believed that the child had some impairment in vision. No stiff neck was noted and there were no convulsions. She became gradually more drowsy and on the day of admission seemed almost semicomatose.

The family history is non-contributory.

The only significant fact in her past history was pneumonia at the age of three weeks which was treated at the Children's Hospital. She had none of the childhood infectious diseases.

Physical examination showed a well-developed and nourished drowsy female child. The pupils were equal and reacted normally. The right ear was negative. No landmarks were seen in the left ear but the drum did not bulge. The pharynx was red and filled with mucus. The tonsils were slightly enlarged and injected. The lungs were clear. The respirations were irregular consisting of about six deep rapid breaths followed by a period of apnea. The heart was not enlarged and no murmurs were heard. The abdomen was negative. The extremities were spastic. The neck was not stiff. The Babinski was positive on both sides and there was also a positive Gordon test. The anterior fontanelle was slightly depressed. The abdominal reflexes were absent. There was a tache cérébrale.

The temperature was 101.5°, the pulse 120. The respirations were 38.

No urine examination was made. The blood showed a red cell count of 5,320,000, with a

hemoglobin of 90 per cent. The white cell count was 17,900, 71 per cent polymorphonuclears. A blood Hinton test was negative.

A lumbar puncture showed a low initial pressure with a slow rise and prompt fall upon right jugular compression and no response upon left. Ten cubic centimeters of clear fluid was removed, there were 14 cells, 8 polymorphonuclears and 6 lymphocytes, the sugar was 74 milligrams per cent, Pandy test was negative, the protein was 30 milligrams per cent and the goldsol was 0011000000, Wassermann test was negative and culture showed large Gram positive cocci.

X-ray films of the long bones were negative. A chest plate was also negative.

She rapidly failed. The temperature rose to 104° on the second day and terminally to 108.2° on the third day.

DIFFERENTIAL DIAGNOSIS

DR. HAROLD L. HIGGINS. This is clearly a child with some cerebral condition. She fell ten days before coming into the hospital. It is true that with practically every patient having a cerebral condition there is the story of some trauma not infrequently irrelevant. In most cases of tuberculous meningitis the parents will look back and recall some sort of fall or blow on the head. The fall of this child was apparently of little significance, so far as we can tell, at least, she did not lose consciousness nor did she become unconscious within the next twelve hours. I should be inclined to feel that the fall had no bearing on the case.

She presents many striking symptoms that indicate pathology in the brain. She was comatose. There may have been impairment of vision. She had a very high fever, and the temperature of 108.2° definitely points toward medullary involvement. She had irregular breathing, apparently the type of Biot rather than of Cheyne-Stokes. Biot's breathing indicates some pathology in or near the medulla. I think the Babinski sign is not significant in young children, one finds a positive Babinski in a large percentage of children one year of age. But the tache cérébrale is usually present in patients with cerebral involvement, we find its absence of value in deciding that a child has not poliomyelitis.

The lumbar puncture report presents some rather contradictory statements. There is no response on left jugular compression. This may make you first suspect that the trouble may be a sinus thrombosis involving the left lateral sinus. However, there are cases in which one fails to get response on jugular compression and in which sinus thrombosis is not present.

The fluid was not under pressure and it had a sugar level of 74 milligrams per 100 cubic centimeters. That is a relatively high sugar and if

the spinal fluid contained bacteria, as is indicated in the last statement, one would expect that the bacteria would have consumed all the sugar in the spinal fluid and the spinal fluid sugar would be practically nil. Also, with such a large number of cocci one would expect a large number of cells. I think we can safely say that the finding of Gram positive cocci in the spinal fluid was due to contamination and probably the cocci were staphylococci. The fluid showed fourteen cells, but practically no increase in protein—a negative globulin test by the Pandy determination. In irritation of the meninges we find that there is an increase in cells and increase in globulin. We have very few cells here and no globulin, I feel there was very little, if any, irritation of the meninges. Occasionally in a poliomyelitis we get a cell count of fourteen with a very small amount of globulin.

The roentgenograms of the long bones were taken, of course, to rule out lead poisoning; no laboratory evidence for lead poisoning was found. The x ray of the chest rules out a general military tuberculosis.

In the differential diagnosis of this case one must consider tuberculous meningitis, however, I think it can be quite readily ruled out, there was no increase in spinal fluid pressure, fewer cells were found than ordinarily seen in cases of tuberculous meningitis, no tubercle bacilli were reported as found and there was no globulin. The spinal fluid findings are not those you would expect in tuberculous meningitis.

Another possible diagnosis is mastoiditis with sinus thrombosis and inflammatory reaction in the meninges. The story of the ear trouble is very minor to expect a sinus thrombosis. The ears seemed pretty normal at admission. She had a running ear a month previously. If it is sinus thrombosis, there might possibly be an abscess in the brain at some distance from the meninges. There might be an abscess outside the dura, but in either of these cases I should have expected more globulin to be present in the spinal fluid. I think mastoid complications are possible but very unlikely. In a child of one year with mastoiditis the inflammation is more likely to extend out so that there is postaural swelling rather than push in toward the lateral sinus and brain. Personally, I feel inclined to believe that the ear is not a responsible factor.

I do not believe cerebral hemorrhage is the factor here. I think we would have found more abnormalities in the spinal fluid.

The spinal fluid findings are as much in keeping with poliomyelitis as anything we have. They might be in keeping with a tumor.

We can pretty definitely say that this child had an encephalitis. I do not think there is very much doubt about that. She was drowsy. She was spastic. She showed probable signs

of loss of vision. Her respiration was irregular. She had a very high fever and showed spinal fluid changes quite in keeping with many cases of encephalitis. Encephalitis which is near the surface of the brain is likely to lead to changes in the spinal fluid. Encephalitis that is far removed from the surface of the brain and the meninges may be accompanied by no change in the spinal fluid at all. I am rather inclined to approach this as a case of encephalitis terminally involving the medulla. To decide the cause of the encephalitis, let us consider what the possible causes of encephalitis are. There is suppurative encephalitis, usually resulting in a brain abscess, I do not believe that is the diagnosis here. We must consider toxic encephalitis due to lead, but there was no lead line found on x ray of the long bones. I presume no stippling of the red blood cells was found. A toxic encephalitis may also be due to bacterial toxins, such as found in typhoid fever, pneumococcus, and bacillary dysentery. We do not seem to find here any definite disease caused by toxin producing bacteria. She did not have dysentery, or typhoid fever. The child had no nutritional disturbance such as might lead to an encephalitis from insufficiency disease (lack of Vitamine B). The encephalitis was not from cerebral anemia. She had a normal hemoglobin and no cyanosis. There is no suggestion of parasites affecting the brain although the data is not 100 per cent complete on that point.

The other type of encephalitis is the encephalitis that accompanies or follows from a virus disease. Practically any of the virus infections may at times lead to encephalitis. Probably the best known of them is poliomyelitis. I am inclined to feel that this case was not due to poliomyelitis or polioencephalitis because of the time of the year, February, which is not the season when poliomyelitis is prevalent. Of the other virus infections, cases are reported where encephalitis occurred with measles, smallpox, vaccinia, mumps, rabies, chickenpox, epidemic encephalitis is presumably a virus disease, this morning I learned of a case of encephalitis in a child with rubella.

I am inclined to think our patient had a virus encephalitis and not poliomyelitis. The virus, I should say, was that of the ordinary grippé. I am inclined to think she got the grippal infection and with it the virus encephalitis. This winter I have seen two small babies who developed convulsions near the onset of a respiratory infection, and it impressed me that they might have had an encephalitic manifestation of ordinary grippé. My diagnosis in this case is, thus, a virus infection (grippé) with encephalitis. This is a diagnosis of something we do not know much about. Most of the encephalitis cases that accompany grippal infections do not

end fatally, the diagnosis could not be proved pathologically. Possibly this is a case where we may get some data on a previously not recognized condition.

DR HAROLD L. HIGGINS' DIAGNOSIS

Virus infection (grippe) with encephalitis
ANATOMIC DIAGNOSES

Encephalomyelitis

Otitis media, chronic, bilateral

Pulmonary atelectasis

Pulmonary edema, slight

Duodenal diverticulum

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: The autopsy on this case was entirely negative except for the finding in the cerebral nervous system. The only things we found in the body were areas of atelectasis and slight edema of the lungs, a very common finding in the terminal stage of a variety of central nervous system diseases. Dr. Kubik will tell you about the brain findings.

DR CHARLES S. KUBIK: There was bilateral otitis media and, as Dr. Higgins suspected, encephalitis or rather encephalomyelitis, since both brain and spinal cord are affected.

Microscopic examination reveals numerous small lesions in the brain, brain stem, cerebellum and spinal cord. A striking feature of these lesions is their perivascular arrangement. In a fair-sized zone around the vessel myelin is destroyed and there is a pronounced glial reaction consisting of proliferation of microglia and probably also of other glial elements. In the zone of demyelination nerve cells are damaged and some are destroyed, axis cylinders are thinned out but a fair number of them are preserved. In the adventitial tissues of the affected vessels there is a cellular infiltration with monocytes, a smaller number of lymphocytes and a few plasma cells. In the forebrain the lesions are most numerous in the subcortical white matter but are also found in the gray matter, in the midbrain gray matter is affected more than the white, while in the spinal cord gray and white matter are affected to about the same extent.

In the spinal cord, in addition to numerous perivascular lesions, there is just beneath the pia a narrow zone of myelin degeneration with glial proliferation having no relation to blood vessels.

The findings here are those of disseminated encephalomyelitis. This condition has been observed most often in association with measles and vaccinia although it may occur, as in this case, with other infections and possibly also without any preliminary disease.

Because the pathology is the same in each case there is reason for suspecting that the causative factor is the same whatever the associated disease may have been, and that measles, vaccinia, or other infection simply constitute a predisposing factor.

Although positive proof is probably lacking

it has the earmarks of an infectious disease, very likely a virus infection.

CASE 21422

PRESENTATION OF CASE

A fifty-one year old Canadian housewife entered complaining of pain in the chest radiating to the arms, of a month's duration.

At the age of twenty-four, approximately twenty-seven years before admission, she noticed the onset of failing vision. Associated with this were severe headache and occasional vomiting. An oculist informed her that very little could be done for her vision. Ten years later, during her first pregnancy, she had frequent daily vomiting, and five months after conception she miscarried. A persistent non-productive cough accompanied this illness. At the time of her miscarriage she had practically no vision at all. She was stone blind for the following eight weeks. There were no convulsions or edema at that time. She was told, however, by a local physician that she had very high blood pressure. Eight months later the patient again became pregnant. She vomited daily and her vision again started to fail. A therapeutic abortion was performed at the end of one month. Her blood pressure was very high even after the abortion. Three years later she had her third and last pregnancy. Associated with this was the usual amount of vomiting but she did not lose her vision. At the end of six months she miscarried. Her blood pressure a week after delivery was 200 systolic. For the next twelve years she was well and symptom free, except for headaches and some slight dyspnea on exertion. One month before admission she noticed a sharp pain in her chest upon climbing stairs. The pain appeared off and on during the day and radiated to both arms. The pain produced a gripping, suffocating feeling in the chest. Her physician found her blood pressure higher than it had ever been. She was put to bed for two days with morphia and for the next three weeks she had the same pain on exertion only in a much milder form. Nine months before admission she had this pain at night associated with gas and relieved by hot water and soda. Her physician gave her morphia. On the morning of the day before admission she experienced sudden pain and numbness in both legs. She was unable to get out of bed, and sweat profusely. The pain in her legs increased and she was brought into the Emergency Ward by ambulance.

Her father died at the age of seventy-five of a stroke. Her mother died at the age of seventy-two also of stroke. Two siblings were living and well.

Physical examination showed a fairly well-developed and nourished, slightly thin, middle-aged woman lying in bed in no acute distress. The skin was cold and slightly moist. The lips were rather deeply cyanotic. The fundi showed marked narrowing of the arteries and distention of the veins. There was a slight exudate

in the macular region of the left fundus. The heart was enlarged to the left, the left border of dullness being 11 centimeters from the mid sternal line, the right 2 centimeters. The rate was 120 rhythm regular. There was a proto diastolic gallop. The sounds were of poor quality. The blood pressure was 180/110. A few medium moist râles were heard at the left base with some bronchovesicular breathing. The abdomen was soft. The liver dullness was down 2.5 centimeters in the midclavicular line. Both lower legs were cold, dusky with a pallid cyanotic line. The feet were not stone cold however, and there was a tinge of pink in each foot which blanched readily on pressure and quickly returned. The dorsalis pedis plantar and femoral were not palpable on either side. There was some hyperesthesia to pinprick.

Examination of the urine showed a specific gravity of 1.030 with a slight trace of albumin and large numbers of white blood cells. The blood showed a red cell count of 4,370,000, a hemoglobin of 70 per cent and a white cell count of 12,000, 88 per cent polymorphonuclears. The stools were negative. A Hinton test was negative. The non-protein nitrogen was 31 milligrams.

Electrocardiogram showed sinus bradycardia, rate 120, left axis deviation and inverted T.

A note was made on the fourth day that both legs and feet had cleared remarkably well. There was no cyanosis and the numbness had almost entirely disappeared. No pulsations however could be felt in any of the arteries. On the sixth day digitalization was begun. Twelve days after admission the heart sounds were poor but the chest was remarkably clear. There was no cyanosis or edema. She became markedly disoriented and confused and was unable to focus her eyes and on the eighteenth day she became almost comatose. Her temperature, pulse and respirations gradually began to rise finally reaching 105°, 158 and 68 respectively on the twenty-fourth day the day of her death.

DIFFERENTIAL DIAGNOSIS

DR. WILLIAM B. BREED. The first part of the history is a fairly straightforward picture of either actual kidney disease or of low functioning kidneys associated with hypertension that cannot stand pregnancy. If she had not become pregnant she might perfectly well have gone for a long time with these kidneys. There are a great many women who have kidneys that will function under normal conditions so that they do not have any symptoms referable to high blood pressure until a lot later but the added burden of pregnancy gets them into trouble. She probably had some essential hypertension ten years before she became pregnant. Then with this story of various pregnancies and break down in function of the kidneys she went along pretty well until she began to get

into trouble from the hypertension itself, and now we read of beginning trouble with the heart on the basis of long standing hypertension.

"The day before admission she experienced sudden pain in the chest and numbness in both legs." That of course brings up the question of dissecting aneurysm on the basis of long standing hypertension with or without some coronary disease. Until you get to the point where this sudden episode occurred the day before admission, your attention is focused on the question of angina on the basis of coronary disease, and of the possibility of her having had a month before a small coronary thrombosis, but there is not enough evidence to tell you whether she did have it or not. The last episode is certainly suggestive of dissecting aneurysm.

There is an arteriosclerotic family history here, but the ages mentioned are so advanced that it is not really significant it seems to me from a hereditary point of view. If her parents had died in the fifties with evidence of arteriosclerosis I think the hereditary factor would be of more importance.

What else have we to consider in this history as regards differential diagnosis? Of course you can put down on paper any number of possibilities such as gall stones or pulmonary infection, which might have caused this acute episode but it does not seem to me worth while making such a broad differential diagnosis, but the story on the whole seems pretty straightforward on a cardiovascular basis.

The physical examination confirms the general impression that we get from the history namely, that she probably had some coronary disease on the basis of long standing hypertension or perhaps a dissecting aneurysm. An electrocardiogram would help us a good deal in ruling in or out coronary disease here. Her blood pressure stays up well. She has not had a severe coronary thrombosis presumably because the blood pressure is reasonably high although of course we do not know what it was when she had her accident.

It is very interesting to see that the renal function, at least as measured by the nitrogen retention test, is as good as it is with that long history in the past of fairly acute renal insufficiency during pregnancy. She had probably had some albuminuric retinitis. It is remarkable how the kidneys will stand a thing like that and return to pretty good function. I think this is unusual however. One would expect that kidneys which had been put to such a strain would not be so good as they are now.

Unless there is something very unusual and hidden in this story it seems to be pretty straightforward. It would be interesting to speculate as to what sort of kidneys you will find here. I think you will find rather small

white kidneys and no acute glomerulonephritis. You will find some coronary disease, possibly an old small coronary occlusion, but I should say no fresh infarct. I should think there might well be a dissecting aneurysm extending a good way down the aorta, possibly down into the iliaes, although inasmuch as the leg has cleared somewhat, one is led to believe that the dissection does not extend down into either of the iliaes. It shut off the circulation however to the extent that it could not be felt.

A PHYSICIAN: What do you think about the urinary sediment?

DR BREED: The large number of white cells does not interest me at all. Presumably there are no casts or red blood cells. You have to assume that. The albumin might perfectly well be on the basis of chronic passive congestion. I do not think that would lead me to make a diagnosis of glomerulonephritis or an acute process. I still think she has a small white kidney.

A PHYSICIAN: How about nephrosclerosis?

A PHYSICIAN: Should she not have a low specific gravity?

DR BREED: I think that is a perfectly good point. There is a high specific gravity.

A PHYSICIAN: It is of thirty years' duration.

DR BREED: Yes, it is a long time. It is possible that you will not find very much vascular nephritis so to speak. But if you do find anything, that is the type of abnormality you will find. Maybe the kidneys are not bad.

A PHYSICIAN: Is it possible that when she had the pregnancy some of each kidney was infarcted but there was left enough good kidney tissue to take care of things pretty well?

DR BREED: I am not quite clear about infarction of the kidney in relation to this sort of story. Are you, Dr Mallory?

DR TRACY B MALLORY: I have seen one case of massive infarction of the renal cortex of both kidneys during pregnancy. It is a very rare but recognized condition.

A PHYSICIAN: Do you associate infarction of the kidney with this kind of story of pregnancy?

DR MALLORY: The condition is not one of isolated infarcts, single or multiple, such as are seen in embolism but rather a massive necrosis of the whole cortex, a condition which could hardly be survived. There is one case on record where massive necrosis of the renal cortex was proved by biopsy yet the patient got well. I think one must assume, however, that the necrosis was incomplete.

DR BREED: If you got to the point of massive necrosis of the renal cortex you would not have this story of ten years' freedom?

DR MALLORY: No. One of the theories of the pathogenesis of the pregnancy kidney is that a diffuse arterial spasm occurs which lasts long enough to cause more or less degeneration of the cortex, usually slight, occasionally massive, according to this hypothesis the pregnancy

kidney represents a reaction to local circulatory lack brought on by very persistent spasm in the smaller renal vessels and the results can naturally be very variable depending on how long the spasm lasts.

DR BREED: So that she might have had periodic spasms associated with pregnancy and not enough to do permanent damage to the cortex. I will be willing to say that maybe the kidneys are not bad except that they will show some result of long-standing hypertension. She is still relatively young, only fifty-one.

DR MALLORY: I should like to ask one question of Dr Breed. Would he not consider it unusual that she should live so long after the acute episode if she had a dissecting aneurysm?

DR BREED: As I have said, I assume because of the improvement after the accident that the dissection was not very low but shut off enough circulation to prevent feeling the arterial beat.

DR MALLORY: Dissecting aneurysm, as we have seen it here, has been a pretty rapidly lethal disease, three to six days.

A PHYSICIAN: Might she not have showered emboli from vegetations upon a valve? She shows some mental symptoms toward the end. She became disoriented and confused and could not focus her eyes, and had paresthesia, too.

DR BREED: I think that is a perfectly good suggestion, that this woman had vegetations in her left auricle and that she did shoot off some emboli. That is perfectly reasonable.

I think I shall have to retract and put it on the basis of vegetations and emboli and thrombosis in the peripheral vessels.

CLINICAL DIAGNOSES

Hypertensive and coronary heart disease
Coronary thrombosis
Cerebral embolism
Arterial (bifurcation of aorta) embolism

DR WILLIAM B BREED'S DIAGNOSES

Hypertensive and arteriosclerotic heart disease
Mural thrombi—left auricle
Emboli in peripheral vessels
Old coronary occlusion

ANATOMIC DIAGNOSES

Coronary thrombosis
Mural thrombus, left ventricle
Ball thrombus, left auricle
Thrombosis of the abdominal aorta, common iliac and internal iliac arteries
Circulatory insufficiency, both lower extremities
Renal infarction, right
Arteriosclerosis coronary and aortic
Arteriolar sclerosis pancreatic, splenic and renal

PATHOLOGIC DISCUSSION

DR. MALLORY We had one dramatic case of dissecting aneurysm that started off with a history almost identical with this and I am sure that was in Dr. Breed's mind. However, this woman did not have one. She had a very severe arteriosclerosis which involved the aorta and the coronaries, and a branch of the left descending was completely occluded. There was a fresh infarct of the heart, possibly a month old, with a thrombus overlying it. There was also another thrombus in the left auricle. The aorta from just below the renal arteries was completely filled with fairly old blood-clot that was beginning to organize. It must have been present from the history about three weeks. It had run down into both iliacs and part way into both femorals.

The heart in spite of thirty years of hypertension was not hypertrophied. The weight was only 325 grams. The kidneys were somewhat small, 175 grams, but she was a very small woman so that is probably not so much atrophy as the weight would suggest. I should imagine that for an average sized individual this would

correspond with kidneys about 200 grams in size. Microscopically they show a benign type of vascular nephrosis, not particularly severe, nothing acute about it, exactly the kidney you would expect to find with long standing, not too severe hypertension.

DR. BREED There is nothing to give any lead as to what the acute episodes in the previous pregnancies may have been?

A PHYSICIAN What did the valves show?

DR. MALLORY They were perfectly normal. The embolus came of course from the left heart, but I cannot say whether it was from the auricular or the ventricular thrombus.

DR. BREED That is what I was going to ask you Dr. Mallory. How do you explain thrombi in the auricles when there is no directly underlying infarct?

DR. MALLORY Of course in any case in whom there is prolonged heart failure with marked dilatation of the auricles and especially fibrillation you get enough stagnation of blood to make thrombosis fairly probable. But in a case like this where you never found a symptom of heart failure, and no fibrillation, I find it much harder to explain. Perhaps she had fibrillated at some time.

THE BERGER RHYTHM AND BRAIN PHYSIOLOGY

THE brain is in a continuous state of electrical unrest. Hans Berger, in recent years, has been able to record the action potentials of the brain and to demonstrate that under standard conditions they are fairly regular in time and equal in intensity. In other words by the use of suitable amplifying and recording devices, a continuous series of rhythms of electrical potential, justly called by Adrian and others the Berger rhythm, may be measured and recorded. These action currents of the brain are comparable to those of the heart which are visualized by means of the electrocardiogram. The new method is termed "electroencephalography." The currents may be led off directly from the brain by electrodes inserted in it, but may be almost equally well obtained from electrodes placed on the scalp. Thus a method has been devised of studying the electrical activity of the brain with an apparatus comparatively easily set up.

The results have been curiously uniform in the hands of various workers. The waves of electrical activity of the brains of different individuals appear similar in their general form, although there may be variations in amplitude. Adrian finds a focus of response in the occipital lobe which may shift from time to time and be greater in some persons than in others. When sensory stimuli induced by sudden light or noise intervene, the rhythmic waves immediately decrease greatly in amplitude. Thinking decreases the size of the waves, but in spite of the many things which decrease or distort them, "at rest" the rhythm is extremely uniform. Few facts at present are known about this surprising electrical rhythm, but as a method of physiological experimentation it would seem that we have a new and important procedure with which to attack the age-old problem of brain function.

The effects on the Berger rhythm by disease processes have begun to be studied. Professor Otfried Foerster of Breslau has used electroencephalography as a means of localizing brain tumors. The work is only in its earliest stages of development and no conclusions of its value can be reached at the present time. Work on epilepsy, however, has progressed farther, especially in the hands of Boston investigators. Working in the Department of Physiology of Harvard Medical School, Drs. Fred Gibbs, Lowell Davis and William G. Lennox have conducted a series of researches on patients with epilepsy. Dr. Lennox presented a résumé of their results at the Second International Neurological Congress, held in London in August of this year.

These studies were largely made on patients with petit mal. A normal Berger rhythm was obtained during quiescent periods, with the exceptions noted below. Proceeding or accompanying the attack, however, the rhythm was greatly distorted, there being a burst of electrical potentials about ten times the voltage and about one-fifth the frequency of the patient's usual potentials. When clonic movements were present, they were synchronous with the large waves, but similar voluntary movements were unattended by differences in electrical potentials. It is interesting to note, moreover, that the form of the large waves was individual for each patient and that some patients, symptom free, showed small disturbances of rhythm suggestive of laval or sub-threshold seizures. States of alkalosis or anoxemia caused the waves to be come slower and larger and if continued till a seizure was induced, the action currents were identical with those which accompanied the patient's spontaneous seizures.

New light is thus thrown upon the complicated problem of the epileptic seizure. Of particular interest are the observations of sub-threshold attacks, a point often considered in

the past but never previously demonstrated. That this new method will open up a wide field of investigation of brain function, both normal and abnormal appears to be a justifiable conclusion from these preliminary studies.

ALLERGY AND "THYMIC" DEATH

A DEGREE of temerity, brazenness or ignorance is necessary even to raise again the question of the enlarged thymus thymic death or status lymphaticus. The subject has been argued from A to amperesand, and the proponents of the theory of thymic death have been regarded by the majority of latter day investigators to a limbo inhabited by the Druids of old and any other upholders of mysticism and superstitious beliefs. The enlarged thymus has been demonstrated by Boyd and others to represent the normal size of the organ in a state of health and Farber has shown that certain cases upposely dying from status lymphaticus had actually succumbed to an acute streptococcus infection.

As is natural with such a sudden and spectacular type of demise hyperallergy and anaphylactic shock have received their share of attention and thus thesis Waldbott¹ supports in an article entitled *The Allergic Theory of So-Called Thymic Death*. Waldbott, having noted on several occasions in allergic families sudden death which presented the clinical and pathologic characteristics of so-called thymic death (enlargement of the thymus gland and other lymphoid tissue and a decrease of medullary substance of the adrenals) reviewed a series of 104 autopsies in which the diagnosis of thymic death had been made. Sixty of these cases were excluded because there were sufficient other indications to account for death. Of the remaining forty four all showed uniform changes in the lungs namely edematous hemorrhagic areas into the alveoli with a more or less severe degree of necrosis. Transmural emphysema alternating with atelectasis was observed, and occasionally eosinophil cells were present. In some cases a secondary enlargement of the right heart appeared to be present and in some hypoplasia of the medullary portion of the adrenals was noted.

These lesions are strikingly different from those of true bronchial asthma but they are those described as the most characteristic changes in the pathology of anaphylactic shock in man, corresponding accurately with those described in death following the administration of tetanus antitoxin. The deductions drawn by this author are that enlargement of the thymus gland may constitute a preallergic phenomenon since true allergic symptoms frequently develop in later years in children who had formerly

had roentgen evidence of an enlarged gland, and that "thymic death" represents a preallergic phenomenon that is probably identical with anaphylactic shock.

It is beyond the boundaries of common sense to assume that all cases of sudden death in childhood attributed to the thymus gland are due to hyperallergy or to any single cause, it is more than reasonable to admit that anaphylactic shock may play the decisive part in many of them.

TREATMENT OF CANCER OF THE FUNDUS OF THE UTERUS

In determining what line of treatment should be undertaken in a case of cancer of the body of the uterus, one must begin by considering what therapeutic procedures are possible Treatment in some form is necessary since the disease does not spontaneously disappear

One thinks of cancer as due to some perversion of the vital processes of the body cells On this account there arises the hope that in some way, at some time, cancer can be controlled by modifying the activity of living cells Various chemicals, especially in the form of elements, have been suggested and tried In spite of much experiment no foundation for the realization of this hope has been discovered Although some favorable results in dealing with cancer in lower animals have been obtained, chemotherapy offers, as yet, nothing for the human patient

Radiotherapy is more hopeful As a rule the type of carcinoma found in the body of the uterus is somewhat radiosensitive, but an obstacle to effective treatment by this means is the practical difficulty of getting the radium close to the growth If the growth is massive, or if a small growth is associated with myomata

*A series of short selected articles by members of the Section will be published weekly
Comments and questions by subscribers are solicited and will be discussed by members of the Section

which deform the uterus, it is not a reasonable expectation that the rays will be thoroughly effective If the growth is small, and the uterus not enlarged, the method may be curative, as shown by recorded cases

More hopeful than radiotherapy is operation, removal of the whole uterus with tubes and ovaries This has given the best gross and corrected results

What should be done in some specific case depends on not only the resources of treatment but also on the case If the risk of operation seems great because of some contraindication as obesity, or heart or kidney disease, it may be better to try radiotherapy, x-ray is steadily becoming a more effective supplement to radium in the uterine cavity If the risk of operation seems not too great, vaginal or abdominal hysterectomy should be employed As a considerable proportion of these patients have never given birth to a child, the vaginal approach is likely to offer more difficulty than in a multiparous woman Whether vaginal or abdominal hysterectomy is performed, the cervical canal should be closed by sutures to prevent escape of uterine contents during manipulation The growth may prove to be more extensive than was suspected at first so that vaginal hysterectomy may become complicated by involuntary morcellation, necessary because of undue traction, but it is a dangerous procedure It is not necessary to make a wide resection of parametrial tissue at panhysterectomy Metastasis is not common and progress of the disease is usually by direct extension The course of the round and especially of the ovarian ligaments should be scrutinized closely for growth It is very unusual to find outward growth as low as the level of the uterine artery where it crosses the uterus

The results of treatment should be studied critically Operation gives the higher immediate mortality and more ultimate cures Radiotherapy may be followed by considerable general disturbance Some patients who have had radiotherapy and later operation, have said that the former procedure made them feel worse than did the operation Perhaps narcotics have produced this mental reaction Pyometra and sepsis may follow radium In any case its use is not to be undertaken lightly

A word should be said as to the treatment of the patient before the lines of therapy noted above are considered it is to make sure the patient has cancer of the fundus of the uterus This disease has no characteristic symptoms Therefore any patient who has symptoms which are found with cancer of the body of the uterus may have that disease In the present state of knowledge of the possibility of danger, it is criminal neglect to refuse to find out what is wrong and to throw out a smoke screen called "change of life" Every year the use of this smoke screen by physicians costs many women their lives

THIRD ANNUAL POSTGRADUATE MEDICAL
EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning October 20

Barnstable

Sunday October 20 at 4 00 P.M., at the Cape Cod Hospital Hyannis. Subject Cancer of Stomach Bowel and Oento-Urinary Tract. Modern Care of the Inoperable and the Incurable the Development of Improved Methods of Caring for these Cases with Less Pain and Discomfort with Minimum of Drug Therapy. Instructors I J Walker and F H. Colby J I B Vall, Chairman.

Bristol South (Fall River Section)

Monday October 21 at 4 00 P.M. at the Stevens Clinic of the Union Hospital Prospect Street, Fall River. Subject Neurological Aids in the Diagnosis and Treatment of Disease from the Medical Viewpoint. Problems of History and Examination with Special Reference to (a) Neurosyphilis Multiple Sclerosis and Other Degenerative Conditions (b) Diseases with Acute Onset, such as Meningitis and Cerebral Accidents. Instructor H R. Viets Eugene A. McCarthy Sub-Chairman.

Essex North

Friday October 25 at 4 00 P.M., at the Hotel Bartlett, 95 Main Street, Haverhill. Subject Cancer of Stomach Bowel and Oento-Urinary Tract. Modern Care of Inoperable and the Incurable the Development of Improved Methods of Caring for these Cases with Less Pain and Discomfort with Minimum of Drug Therapy. Instructors E G Crahtree O O Land and H. F. Friedman Francis W Anthony Chairman

Essex South

Tuesday October 22 at 4 00 P.M., in the Nurses Home of the Salem Hospital Salem. Subject Cancer of Breast and Uterus Sarcomas of Bone Lymphoma and Leukemia Their Early Diagnosis Discussion of Life History of Cancer and Grades of Malignancy. Instructors J V Meigs, C E. Dumas and Dudley Merrill. Walter G Philpen Chairman

Hampden

Thursday October 24 at 4 00 P.M. at the Academy of Medicine Professional Building 20 Maple Street, Springfield and at 8 00 P.M. at the Holyoke City Hospital Holyoke. Subject Kidney and Bladder Diseases A Acute Nephritis — Etiology Diagnosis and Treatment. Nephrosis and Its Treatment. (Medical.) Instructor E. M. Chapman

George L. Schadt and George D. Henderson, Chairmen

Hampshire

Wednesday October 23 at 4 15 P.M., in the Nurses Home of the Cooley Dickinson Hospital Northampton. Subject Cancer of Breast and Uterus Sarcomas of Bone Lymphoma and Leukemia. Their Early Diagnosis Discussion of Life History of Cancer and Grades of Malignancy. Instructors G W Taylor and E. M. Chapman. Robert B Brigham Chairman.

Middlesex East

Wednesday October 23 at 4 00 P.M. at the Melrose Hospital Melrose. Subject Lung Diseases (a) Differential Diagnosis and Treatment of Lobar Pneumonia. (b) The Surgical Problems of Empyema. Instructors Maxwell Finland and R. H. Overholt. Joseph H. Fay Chairman

Middlesex South

Tuesday October 22 at 4 15 P.M. at the Cambridge Hospital Cambridge. Subject Psychiatry Management of Psycho States in the Care of General Diseases Especially Chronic Disorders Subpsychotic States. Instructors O C Canor and Maurice Fremont Smith Edmund H. Robbins, Chairman.

Norfolk South

Monday October 21 at 8 30 P.M., at the Quincy City Hospital, Quincy. Subject Diseases of the Liver Hepatitis and Painless Jaundice Problems in Diagnosis and Treatment. Instructors Channing Frothingham and E. L. Young David L. Belding Chairman.

Plymouth

Tuesday October 22 at 4 00 P.M., at the Brockton Hospital Brockton. Subject Ophthalmology and Otolaryngology (a) The Major Hazards in Diagnosis of Diseases of the Eye, Ear, Nose and Throat as Seen in General Practice (b) Special Treatment in Acute Medical and Traumatic Diseases of Eye Emergencies Arising in the Treatment of the Ear, Nose and Throat. Instructors F L. Wellie and T. Gundersen. W H Pulsifer Chairman

Worcester North

Friday October 25 at 4 30 P.M., at the Burbank Hospital Fitchburg. Subject Syphilis Modern Treatment. The Use of Neosalvarsan, Tryparsamide, Bismuth Mercury Potassium Iodide, etc., in Office Practice. Gonorrrhea Treatment of Complications as Seen in General Practice. Instructors O F Chx, Jr., and A. W. Cheever Edward A. Adams Chairman.

UNITED STATES EMPLOYEES' COMPENSATION
COMMISSION
Washington

September 19, 1935

From United States Employees' Compensation Commission
To State Works Progress Administrators and Federal Establishments having Employees receiving Security Wages under the Emergency Relief Appropriation Act of April 8, 1935
Re Endorsement of Vouchers for Medical, Hospital and Allied Services

The Rules and Regulations No 1, issued by the Commission July 15, 1935, governing compensation and medical treatment for Works Progress Administration employees, requires that all vouchers, Form S-69 for medical services and all services in connection therewith be endorsed by the Local Compensation Representative (See Paragraph 15 of Rules and Regulations No 1) In Federal establishments the Official Superior is regarded as the Local Compensation Representative for purposes of Rules and Regulations No 1, and the Official Superior's endorsement on the Form S 69 will meet the requirements of Paragraph 15 of Rules and Regulations No 1

Many physicians have been submitting vouchers and bills for medical treatment direct to the Commission This procedure should be discouraged, since it results in unnecessary delay and expense

occasioned by the necessity of returning such vouchers for endorsement by the Local Compensation Representative or the Official Superior of the injured employee, as the case may be

All physicians, hospitals, and all others submitting charges should be instructed to submit vouchers Form S 69, to the Local Compensation Representative, or in the case of Federal establishments, the Official Superior of the injured employee, who in turn should see that the services were authorized, charges are itemized on Form S 69, and signatures are proper, before endorsing the voucher and transmitting it to the Commission Written authorization, if not previously submitted, should accompany the voucher for services

Attention is particularly invited to Sections IV and V, Paragraphs 8 to 36 inclusive, of Rules and Regulations No 1 for detailed information.

The earnest cooperation of all persons concerned is essential to expedite adjustment of medical and other charges by this office

Special Bulletin WP No 1

CORRESPONDENCE

WHERE STATE MEDICINE IS A BOON

Editor, *New England Journal of Medicine*,

In the midst of our discussions of the high cost of modern specialized medical service, it may be of interest to note the existence within a thousand miles of Boston of a region where the problem is to obtain any medical service at all The whole world is familiar with Dr Grenfell's medical mission to the fishermen of the Labrador and northern Newfoundland The eastern section of Newfoundland is taken care of through close communication with St. John's, but there is a section of the southwest coast which is without help from either of these sources Scattered along about 150 miles of coast, running eastward from Cape Ray, are a number of fishing villages totalling in population some ten thousand persons

Although distinctly limited in its economic life this region has been settled by English speaking people for many generations, and is by no means devoid of culture The children have reasonable opportunities for schooling, at least through the primary grades, and the percentage of illiteracy is not particularly high The people are not without benefits of the clergy, and every community of more than a few hundred people has at least one church Yet medical service is limited to one doctor in Port aux-Basques, and the nearest hospital is either six hours north on the railroad, or a nights sail across to Cape Breton Island, trains and boats run three times a week to these points

Transportation along the coast is slow and difficult. A regular steamer service runs every two weeks, otherwise the only transportation is by fishing boats, which travel about four or five miles per hour at a cost of some twenty cents per mile for gasoline alone Fog prevails about 70 per cent of the time, making travel dangerous along the irregu-

lar rocky coast, and night travel is utterly impossible.

Rose Blanche a typical community of twelve hundred people used to have a doctor and nurse up to five years ago. Before the depression when fish commanded a good price the traditional system of private practice was efficiently remunerative to maintain the inhabitants and the community was as well served as it could be by one competent general practitioner. With the coming of hard times there began a series of medical economic changes which are interesting to compare with the various remedies which have been proposed for our own difficulties.

Learning that the doctor was having trouble making both ends meet and was considering leaving town, some of the more enterprising of the citizens proposed the scheme of having each family pay the doctor an annual fee the only extra charge to be for medicine. About half the town joined this scheme and for a year it was quite successful (Health Insurance). However after the first year many of the citizens, finding that they had not needed his services dropped out of the scheme and things became difficult again. As hard times increased came government relief in the form of the dole and when those on the relief rolls were sick the doctor was paid by the government for his services (quite similar to our own ERA scheme).

This system worked reasonably well until the doctor became corrupted and was discovered turning in to the government larger accounts than the services he had rendered warranted. Then he was dismissed from the town and there has been no doctor in residence since. At the present time a single visit from the nearest doctor (when he is available) costs about forty dollars which approximates 10 per cent of the annual cash income of the average family. To go to visit the doctor in his office means a day's trip at a minimum cost of ten dollars besides the doctor's fee. To get to a hospital takes three days on the average although there are times when, with prompt connections the trip can be made within twenty-four hours. It is small wonder that several of the fishermen with whom I talked had lost wife or child from appendicitis operated on too late to save them. All obstetrics is apparently done by one local untrained midwife.

Into this situation now enters that dread demon State Medicine. The government taking pity of the plight of these people is now in the act of building three cottage hospitals on the coast and has already placed in operation this last week a hospital ship carrying the doctor who is in charge of these hospitals and who makes visits in the various settlements when summoned carrying the patient to a hospital when necessary. This hospital ship is a refitted former New Yorker's yacht, which is well suited to the coast conditions and can reach nearly all of the communities along it within a few hours time.

As I was passing through this particular town a few days ago I was asked to see a woman who had

been taken acutely ill that morning with a severe infection of her leg. After giving the best advice I could I suggested that they telegraph (wireless) for the hospital ship the Lady Anderson. Two hours later as I was chugging out of the harbor in a fishing smack we passed the Lady Anderson just coming in. There was something impressive even thrilling about the sight of that little ship which would convince even the most ultraconservative that for this particular community State Medicine was going to prove a blessing.

JAMES H. TOWNSEND M.D.

LADIES HELPING HAND HOME FOR JEWISH CHILDREN

October 1 1935

Editor *New England Journal of Medicine*

The Ladies Helping Hand Home for Jewish Children desires to call to your attention the continuance of its health program for undernourished Jewish children as announced to you in previous communications.

We are also equipped to care for those children who need convalescent care during their recovery from operative procedures and severe illnesses.

This program includes a definite schedule of medical care, rest, diet and recreation, under the supervision of our medical nursing and consulting staffs.

This service is intended for such worthy patients as may come within the above specifications.

Applications may be procured by writing to the Ladies Helping Hand Home for Jewish Children.

Sincerely yours

MRS. MAURICE SAFERS, President

35 Chestnut Hill Avenue
Brighton, Mass.

A HANDBOOK OF COMMUNITY RESOURCES

The Commonwealth of Massachusetts
Department of Public Health
State House, Boston

September 30 1935

Editor *New England Journal of Medicine*

There has come to my notice an editorial in a recent issue of *The New England Journal of Medicine* urging that there be made available for physicians a handbook of community resources. You have pointed out the valuable service rendered locally by the handbook published by the Massachusetts General Hospital and have felt that an enlargement along this line to serve the State would serve a similar purpose.

Throughout the past year this Department has been working on a handbook of this nature which is now in the hands of the printers. We hope it will appear as an issue of *The Commonwealth* during the present year and that it will be possible for us to send a copy to every physician in the State. For various reasons a book published by the Massachusetts cannot cover all of the field included in the Massachusetts General handbook. At the same time however it should contain and we hope that in this instance it does much additional information that

more properly belongs in this type of a publication. The Department realizes that at best such a publication is an incomplete guide to community resources, but has felt that in this first issue it should confine itself pretty largely to public health and related subjects rather than to some of the more detailed problems that have a personal rather than a community bearing. I trust that this handbook when it is ready will fill a useful purpose in this State.

Very truly yours,

HENRY D CHADWICK, M.D.,
Commissioner of Public Health

SIXTY SEVEN TAPPINGS

September 19, 1935

Editor, *New England Journal of Medicine*,

Apropos of the letter of Dr Coues in your issue of September 12 regarding an epitaph in England which he considers an "all time record" of "Tapping." This must be true in one way because 310+ gallons in 28 operations would mean an average of somewhat over 11 gallons a tap.

I venture to send you a copy of an epitaph on a gravestone, in an old churchyard at Kensington, N H. It is partly obscured but I am able to make out the following words:

Benjamin Rowe, Esq

who after a life of great suffering departed
1790—in the 71st year of his age

He was tapped 67 times and from his body
was drawn 2385 pounds of water

Very truly yours,

THOMAS W LUCE

Portsmouth, N H

RECENT DEATHS

FITZ SIMMONS — HENRY JOSEPH FITZ SIMMONS, M.D., of 857 Centre Street, Jamaica Plain, and an office at 370 Commonwealth Avenue, Boston, died at his home, October 5, 1935. Dr Fitz Simmons was born in 1880 and graduated from the Harvard Medical School in 1908.

He joined the Massachusetts Medical Society in 1910 and was also a Fellow of the American Medical Association and the American College of Surgeons. He specialized in Orthopedic Surgery, and served on the Staff of the Children's Hospital since 1912.

MAY—JOHN SHEPARD MAY, M.D., of 20 Lockstead Avenue, Jamaica Plain, with an office at 90 Warren Street, Roxbury, died suddenly October 10, 1935.

Dr May was born in Augusta, Maine, in 1870, the son of John H and Ellen F (Guild) May. His preliminary education was acquired in the public schools of Augusta and the Boston Latin School. He graduated from Bowdoin College in 1893 and from the Jefferson Medical College in 1897. After receiving his medical degree, he settled in Roxbury

where he practiced the remainder of his life. He was a Fellow of the Massachusetts Medical Society and the American Medical Association and a member of the West Roxbury Medical Association.

Dr May is survived by his widow, Mrs Helen E (Lovell) May, a sister, Mrs C H Blackington, of Weymouth, and a brother, Charles L May, of Winthrop.

PARKER—WALTER HENRY PARKER, M.D., of Brewster, Massachusetts, died suddenly at his home, October 12, 1935. He had practiced in Dorchester, Massachusetts, previous to 1925.

Dr Parker was born in 1872 and graduated from the Baltimore Medical College in 1896. He joined the Massachusetts Medical Society in 1899.

He began his practice in Coventry, Vermont, his native town, but soon moved to Dorchester, Massachusetts, where he built up a large practice. He was prominent in Masonic and Odd Fellow Societies.

Dr Parker is survived by his widow, Mrs Ida (Creelman) Parker, and two daughters, Mrs Madeline P B Fee of Hartford, Connecticut, and Mrs Isabelle P Rice of Medford, Massachusetts.

MacDONNELL—JOHN MACDONNELL, M.D., of 536 Broadway, South Boston, died at his home, October 11, 1935, after a long illness. He was born in Ireland, the son of Matthew and Mary (Farley) MacDonnell.

He received his M.D. degree from the College of Physicians and Surgeons (Boston) in 1894 and settled in South Boston.

He is survived by three sons, five daughters, a sister and two brothers.

OBITUARY

DR JOHN J MANGAN

In the passing of Dr John J Mangan, the Staff of the Lynn Hospital loses one of its oldest, as well as one of its most conscientious members.

Dr Mangan, for a long period, devoted his professional activities to Pediatrics and for many years served the hospital in this department. His interest was sincere, and his handling of these little patients was always gentle and considerate.

Above all else, Dr Mangan was a scholar, and wrote upon a variety of subjects. His *magnum opus* was his life of Erasmus, in the preparation of which he spent several years traveling extensively in Europe, tracing and visiting the various abodes of this noted Ecclesiastic.

This monumental work brought to him the world-wide recognition of scholars, and for his achievement he received both honorary degrees and medals.

By his colleagues he is best remembered for his mild and courteous demeanor and his earnestness of purpose.

The Staff has lost a scholarly and cultured mem-

ber and the hospital a faithful worker and an influential friend

WILLIAM T. HOPKINS, M.D.
Memorial Committee.

NOTICES

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 P.M. on Thursday, October 24, in the amphitheater of the Peter Bent Brigham Hospital Dr. Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physics in the Harvard Medical School, will give a medical clinic. To it are cordially invited practitioners and medical students. These clinics will be repeated on Thursdays, October to May.

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12 staff rounds will be conducted by Dr. Christian.

ANNOUNCEMENT

JACOB I. ABRAMS, M.D. has opened an office at 311 Commonwealth Avenue, Boston.

BOSTON UNIVERSITY SCHOOL OF MEDICINE SURGICAL CLINICS AT THE BOSTON CITY HOSPITAL

Friday, October 18, 12:1 Cheever Amphitheatre
Dr. Arthur R. Kimpton, Surgeon-in-Chief, Fourth Surgical Service, Boston City Hospital, will talk on "The Surgery of the Spleen."
Physicians and medical students are invited.

Friday, October 25, 12:1 Cheever Amphitheatre
Dr. William R. Morrison, Associate Professor of Surgery, will present the following cases:
1. Perforated ulcer of the stomach and duodenum
2. Pancreatitis.
3. Empyema of the gallbladder
Physicians and medical students are invited.

A DOCTOR WANTED

Ohsbeague Island, Maine, is in need of a good physician at once. The town pays a yearly salary of \$1,000 in addition to what a doctor can earn. The winter population is around 400 with an additional 1,000 in the summer season. Apply to the Selectman.

REPORTS AND NOTICES OF MEETINGS

FAULKNER HOSPITAL CLINICAL MEETING

The October clinical meeting was held on Thursday, October 3, at 5:00 P.M. at the hospital.

During the summer an unusual number of cases have come to autopsy in which thrombosis of arter-

ies or veins had been the primary disease which eventually led to death. Three cases from this group were selected: the oldest, seventy-eight years of age, and the youngest, thirty-three years of age. In the patient seventy-eight years of age, shortness of breath was the first symptom and within a few days the patient had died with what was presumed to be myocardial weakness and terminal bronchopneumonia. At the postmortem examination pulmonary infarctions were present and were the cause of death. These infarctions came from emboli which originated in the uterine and pelvic veins. No cause for the primary thrombosis in these veins could be made out. Another patient, about fifty years of age, entered the hospital in a comatose condition. Examination of the nonprotein nitrogen in the blood ruled out uremia and it was felt that the patient had some type of vascular accident within the skull. At postmortem examination a thrombosis of an artery at the base of the brain with softening of the area supplied by this artery was found. No cause for the thrombosis was made out. The third case was in a young man of thirty-three years of age who had gradually increasing shortness of breath with sudden attacks of dyspnea and cyanosis over a period of six weeks. The possibility of coronary thrombosis was considered during life. At autopsy old and fresh infarctions of the lung were found with a large embolus in the pulmonary artery. Some hypertrophy of the right side of the heart was present. The source of the emboli was from prostatic veins and the veins around the rectum. There were no hemorrhoids. No cause was made out why thrombosis should have taken place in these veins. The hypertrophy of the right side of the heart was of interest. Although some of the infarctions were probably of six weeks' duration, an x-ray picture of the chest taken three weeks before death did not suggest any appreciable infiltration in the lungs except for one small area. It is interesting to speculate if this hypertrophy of the right side of the heart could have developed within two or three weeks as the increased resistance to the circulation in the pulmonary arteries gradually developed over that time.

Following the presentation of these cases, Dr. Eugene E. O'Neill talked about certain features of vascular disease. He was unable to throw any light upon the etiology of this type of thrombosis in veins and arteries but took up the problem of the prevention of thrombosis in general, especially postoperative and postoperative. He emphasized the importance of placing the patient in the Trendelenburg position with an elevation of ten to twelve inches if it was practical in relation to the type of operation. He urged active and passive exercises as soon as possible after the operative procedure. He has found practically no value in the use of drugs and is not convinced that thyroid extract or hirudin are of any real use. He considers that the reduction of trauma at the time of operation has been overemphasized and doubts the importance of

infection and seems to think that there is as much thrombosis in non-infections cases as in infectious ones. After thrombosis has developed, he feels that the procedure varies with the location of the thrombosis, and separates a thrombosis in superficial veins from that in the deep ones. Although emboli from thrombosis in superficial veins frequently produce pulmonary infarctions, these infarctions are rarely fatal. On the other hand, if it is possible to tie the vein above the thrombosed area he recommends doing so and in occasional instances, he favors injecting into the vein a sclerosing substance between the clot and the blood stream returning to the heart. In thrombosis in the deeper veins he favors motion in the active stages rather than fixation of the part.

Then Dr John Homans gave his views about thrombosis and like Dr O'Neil did not have any suggestions in regard to what is the real etiological factor in these cases. He called attention to the fact that thrombosis is increasing and thought it might be due to stasis produced by keeping patients too quiet. He emphasized that dehydration, trauma and general debility were contributing factors. When trauma is a factor in thrombosis he suggested the possibility of some substance from the injured muscles being a factor in production of thrombosis. He reported on the work of Dr Frederick W Bancroft of New York, who in his attempts to prevent thrombosis after surgical procedure is careful not to place any tight dressings on his wounds. Dr Bancroft also favors starting up peristalsis early and paying particular attention to the avoidance of dehydration. Furthermore, this surgeon recommended the use of sodium thiosulphate intravenously not only as a preventive measure against coagulation but even after thrombosis has developed. Dr Homans gave the impression that he was not quite so much in favor of active motion during the early stages of a deep phlebitis as Dr O'Neil appeared to be, but rather favored giving a chance for the process to subside during a rest period. He thought the term propagating thrombus was unfortunate because it implied that the process was still one of thrombosis when in reality the propagating thrombus is really a clotting of the blood in the main blood stream. If the process of thrombosis extends to a large vein with an active blood current, at this point the process either stops or else clotting occurs in the main blood stream and this clotting frequently develops into a pedunculated blood clot swinging in the blood stream. When this takes place emboli are sure to eventually develop unless the vein is tied off proximal to the clot. These large clots are the ones that produce fatalities by emboli. Dr Homans also called attention to the length of time a good size embolus can persist at the bifurcation of the pulmonary artery without causing complete obstruction and death. In some of his cases the evidence pointed to the embolus having been at this point for a matter of days or even weeks before finally causing death.

THE CARNEY HOSPITAL CLINICAL MEETING

The second clinical meeting of the Carney Hospital was held October 7, 1935, at 8 P M. Dr William J Macdonald spoke on "The Diagnosis of Common Skin Diseases." His talk was profusely illustrated with lantern slides. Dr Macdonald emphasized the important rôle played by eczema in the practice of the dermatologist. This disease comprises forty per cent of the work in the average dermatological clinic. He stated that eczema could not be classified as a simple infection. Idiosyncrasies and allergy are the etiological agents behind a great many of these cases. Dr Macdonald illustrated the damage done by face powders, perfumes, jewelry, furs, plants, and food products. He was very emphatic in expressing his belief that it was highly important to have an internist in consultation on a great many dermatological patients.

Dr Louis E Phaneuf spoke on "The Diagnosis and Management of Pelvic Inflammation." He stated that this condition is the most important of the seven large gynecological divisions. Tuberculosis and gonorrhea are the commonest infections in the female genital urinary tract. He divided the general pathology into three subdivisions, the acute, the spreading, and the degenerative. In the first two stages conservative treatment is the ideal. In the third an operation is usually necessary. Fifty per cent of his patients do not come to operation when treated by the standard conservative methods. He also spoke on the vaginitis caused by the *Trichomonas vaginalis* and gave several methods of treatment. He gave examples from his own private practice and showed analytical lantern slides.

WILLIAM HARVEY SOCIETY

The next meeting of the William Harvey Society will be held Friday, October 25, in the Auditorium of the Beth Israel Hospital, Boston, at 8 00 P M.

PROGRAM

Speaker Dr Walter C Alvarez, Mayo Clinic.

Subject "Functional Digestive Disorders"

Chairman Dr Louis F Curran, Professor of Clinical Medicine, Tufts College Medical School.

SUFFOLK DISTRICT MEDICAL SOCIETY

PROGRAM OF MEETINGS

October 30, 1935

Stated Meeting Boston Medical Library

"The Interpretation of Problems in Bright's Disease and Related Conditions" Dr Soma Weiss

"The Management of the Problems in Bright's Disease and Related Conditions" Dr Laurence B Ellis

Discussion Dr George Gilbert Smith and Dr Louis E Phaneuf.

December 11, 1935

Joint Meeting with the New England Heart Association at the Boston Medical Library

"Constrictive Disease of the Pericardium Dr Charles Sidney Burwell.
Discussion Dr Edwin D Churchill and Dr Paul D White

January 29 1936

Joint Meeting with the Boston Medical Library at 8 Fenway

"Observations Around the World Dr Walter B. Cannon

March 18, 1936

Meeting at the Boston Medical Library

"The Laboratory and Clinical Story of Fatigue." Dr Arlie V Bock and Dr David B Dill.

Discussion Dr Donald J McPherson and Dr Augustus Thorndike Jr

April 29 1936

Annual Meeting at the Boston Medical Library
"The Treatment of Septicaemia. Dr Champ Lyons

"The Plenitude of Scarletina Streptococcus Toxin" Dr Sanford B Hooker

Discussion Dr Hans Zinsser

The medical profession is cordially invited to attend all of these meetings.

CARNEY HOSPITAL CLINICAL MEETING

MONDAY OCTOBER 21, 1935 8 P.M.

Diagnosis and Management of Acute Appendicitis Dr C. McK. Fraser

Treatment of Burns. Dr R. H. Aldrich Lantern Slides

Physicians and medical students invited

MASSACHUSETTS PSYCHIATRIC SOCIETY

The eleventh annual meeting of the Massachusetts Psychiatric Society will be held at the Parker House on Tuesday October 29 at 8 30 P.M. After a business meeting, which will include the election of officers for the coming year the Society will hear the annual discourse which will be given by George Barton D.Sc., Associate of the Carnegie In-

stitution and Editor of *Ipsi*. He will speak on Genius with Special Reference to Science and Music.

OSCAR J. RAEDER, M.D., *Secretary*

NEW ENGLAND HEART ASSOCIATION

The first meeting of the New England Heart Association will be held Monday October 28 in the Ether Dome of the Massachusetts General Hospital, at 8 15 P.M.

PROGRAM

1 Pathological Specimen—Chronic Constrictive Pericarditis. Dr P. D. White.

2. Funct and the Left Pericardial Diaphragmatic Angle. Dr Sylvester McGinn

3 Congenital Heart Disease

A. Unselected Cases for Diagnosis Dr P. D. White

B. Our Experience at the Massachusetts General Hospital in the Past Ten Years as to Accuracy of Diagnosis Dr McGinn.

4 Pulmonary Infarction Complicating Severe Chronic Mitral Valve Disease with Fibrin Dr H. B. Levine

5 A New Method in the Treatment of Paroxysmal Tachycardia. Dr H. B. Sprague.

6 The Normal Lead IV. Dr R. E. Glendy

7 The Abnormal Lead IV. Dr A. Grabiel

The members of the New England Heart Association and interested physicians are invited to attend.

JAMES M. FAULKNER, M.D. *Secretary*

NEW ENGLAND SOCIETY OF PSYCHIATRY

The New England District of the American Psychiatric Association will meet at the Medfield State Hospital Medfield Massachusetts, Thursday October 24 1935

PROGRAM

Buffet lunch will be served at 12 30 P.M.

Business meeting at 1 30 P.M.

Candidates for membership proposed at the last meeting, and approved by the Executive Committee to be presented for election.

Speaker "A Recent Court Experience." L. Vernon Briggs M.D., Boston Mass.

HORACE G. RIPLEY, M.D., *President*

HARLAN L. PAINE, M.D. *Secretary-Treasurer*

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance) Tuesday evening October 22 at 8 15 P.M.

WORCESTER NORTH DISTRICT MEDICAL SOCIETYOctober 23—Quarterly Meeting to be held at the State
Colony in East Gardner, at 4 30 P.M.**BOOK REVIEWS**

**Arthritis and Rheumatoid Conditions Their Nature
and Treatment.** Ralph Pemberton Second Edi-
tion 455 pp Philadelphia Lea & Febiger \$5.50

This is one of the best of any single treatise on
arthritis published to date. It is composed prac-
tically of summaries or abstracts from other men's
works in combination with the author's own observa-
tions. It goes into sufficient detail of the pathology
of arthritis the history is minimized as it should
be. Symptomatology and treatment are well pre-
sented, because they are presented from an intern-
ist's point of view of a disease which primarily be-
longs in the field of internal medicine.

In reading the book, two things strike one who is
really interested in arthritis. First, the statement
that the author's own experience corroborates that of
Nichols and Richardson in the belief that there may
be only one arthritis, but that many individuals re-
act differently and require different forms of treat-
ment at different stages of the joint involvement.
Secondly, no mention is made of the value of con-
tinuous follow-up, or survey, of either the author's
own or other patients. In any study of the ar-
thritic problem, a continuous follow-up of the same
group of patients is of the utmost importance.

Whereas Pemberton in this second edition makes
definite statements regarding the futility of classi-
fication of the arthritides, one is impressed with the
fact that the man is attempting to state in a similar
fashion, but does not do so, that the arthritic is an
individual who has a definite complaint, i.e., some dis-
turbance of the articular or periarticular structure,
which changes as the years go on, or which spon-
taneously arrests itself at any stage after the onset,
or with partial or complete disability and deformity,
or with only such remnants of the disease that
normal function of the impaired joint is reestablished
and no evidence of arthritis can be proved.

The author has avoided or purposely omitted a
great many of the rather exaggerated statements
appearing in books dealing with arthritic conditions

and other joint disturbances from a purely one man point of view either surgical or orthopedic. The book is one that the reviewer believes may be called a four star book. It is a well rounded general presentation of arthritis of the present time. The bibliography is of particular value because it brings up to date in a most comprehensive manner all the literature on the subject published to date. It is highly recommended to anyone interested in the general problem of arthritis as a book which should be bought and kept for practical use.

Some Thoughts of a Doctor Frederick Parkes
Weber 183 pp London H. K. Lewis & Co., Ltd
6s net

"Some Thoughts" comes from the facile practiced pen of a man who has written on many subjects lay and professional for thirty years. From his broad clinical experience with many minds and many men he has collected these observations that set one thinking. The book is to be taken in divided doses but the essays are short many of them too abridged from more extensive ones. For a ten minute sitting it is ideal. "Reminiscent of another learned physician Sir Thomas Browne they are the outcome of a charming and generous personality the expression of one who has achieved a real philosophy of life.

Awaken Your Sleeping Beauty Lilyan Malmstead
96 pp New York E. P. Dutton & Co., Inc. \$1.75

This small book of less than 100 pages is written by the originator of a certain type of exercises. It is quite evident that the author believes in them with an almost religious fervor. The awakening of the sleeping beauty of one's body and individual members is by acquiring erectitude. "Lengthen the line between the chin and waist and you will lengthen your years," says the title page and throughout the book if we follow this advice and bend backward from the waist line we are promised fair bodies and fair minds. We must think erectitude, conceive erectitude, cherish erectitude, express erectitude, glorify erectitude and be glorified by it. "It is the first step to perfect health and is a positive guarantee to keep it." It all sounds very simple and the frontispiece of Miss Malmstead is an excellent advertisement for her system perhaps a better one than the drawings illustrating her exercises.

Erectitude as contrasted with static erectness entails heading backward. The medical man however sees many more ills from exaggerated lambar lordosis than from too little especially in middle-aged persons. A word of caution might not be amiss, suggesting the wisdom of a tempered enthusiasm on the part of the elderly and obese in carrying out the exercises proposed.

Whatever one may think of the method, the message of the book needs transmission. It is undoubtedly true that most people think too little of their muscles and their carriage and because of this thoughtlessness deny themselves both better

health and greater grace. There is little the doctors can do about Miss Malmstead's system except practice the method themselves if they wish and advise their patients to buy "Awaken Your Sleeping Beauty" for after THE END comes the following sentence: "The system of exercise covered by this book was originated by the author. Notice is hereby given that the author will promptly prosecute anyone who without express authorization from the author teaches or attempts to teach such system."

Transactions of the American Association of Genito-Urinary Surgeons. Forty-sixth Annual Meeting held at Hot Springs Va., May 14 15 and 16 1934. Volume XXVII 438 pp Saint Paul and Minneapolis The Brace Publishing Company

The American Association of Genito-Urinary Surgeons is composed of about eighty of the leaders in genito-urinary surgery in this country—and a few distinguished foreigners—and therefore the transactions of its annual meetings represent the views of these leaders. This volume of 438 pages contains thirty articles by different members (and their co-laborers) most of them making genuine contributions to various aspects of genito-urinary surgery. Some papers report brand new work some of it still in the experimental and unproved stage others present rare and interesting cases while still others make their contribution by reviewing or shedding new light on old problems. As in all branches of surgery nowadays there is increasing emphasis on physiological and endocrinological methods of approach and on long time end results, and less emphasis on the purely mechanical and technical aspects. Subjects which particularly attracted the reviewer's interest were the question of the control of prostatic hypertrophy by the administration of hormone, the relation of hyperparathyroidism to the formation of certain urinary stones, the rôle of radiation therapy in the treatment of tumors of the testis and the gonadotropic hormone in the urine of men with such tumors. *Ipso facto* this volume represents the views of the leaders of American genito-urinary surgery.

A Record Book for Tuberculosis Patients. Lawson Brown. New York National Tuberculosis Association. \$1.50

This record book is designed to help patients to keep in close touch with their physicians. I presume under circumstances when for reasons of distance or economy a patient cannot see his physician so often as would otherwise be the case. A typical page consists of a temperature and pulse chart and on the opposite page headings such as "General Symptoms" which include "appetite," "digestion," "strength," etc., and "Localizing Symptoms" under which are "cough" and "expectoration," followed by a few general headings such as "number of hours in bed," "amount of exercise," etc.

For a certain type of patient this little book will undoubtedly be of value for others of the more in

telligent class it is rather too detailed and in many cases quite unnecessary. It closely resembles the "Record Book" used by Dr. Joseph H. Pratt in the Emmanuel Church Tuberculosis Class when the home treatment of tuberculosis was almost the only way in which that disease could be treated. At the present time with what might be called almost a plethora of sanatoria and institutional facilities the scope for such a book as this is limited. The writer of this review uses a form for this identical purpose which is far simpler and which he believes on the whole is better. It is particularly valuable for patients who see him only once a month or thereabouts so that these weekly reports keep him in close touch with the patient. All such means of doing this are steps in the right direction, however, and as such this record book is of value in certain cases.

A Synopsis of Regional Anatomy T. B. Johnston
Third Edition 460 pp Philadelphia Lea & Febiger \$4.50

Previous editions of this valuable textbook of regional anatomy have been favorably reviewed in the *Journal*. In this third edition the general plan of the work has not been modified, but a new section dealing with Osteology has been added. Sections on the brain and spinal cord have been rearranged and in several places rewritten, and the references to the development of various structures have been increased in number and have been inserted in the description of the regions with which they are concerned. The book is preceded by a glossary of the principal alterations of the B. N. A. terminology as approved by the Anatomical Society of Great Britain and Ireland. Although there are only eleven illustrations in the text, they are well selected and seem adequate for the purpose of the book, which is not that of a complete textbook but rather as a manual of review for those who have studied the subject in a larger text and have already performed the usual dissections. Although of British origin, the book is thoroughly and equally well adapted to the use of American students.

Précis de Thérapeutique et de Pharmacologie
Septième Edition A. Richaud et R. Hazard 1257 pp Paris Masson et Cie, éditeurs 100 fr

Richaud and Hazard's publication on pharmacology and therapeutics has for years been a standard text. The seventh edition of their work although a complete revision of the preceding editions, contains all of their completeness and simplicity of form. Embodied are the many new contributions to the above fields. The vitamins, hormones, cholines and vaccines all receive thorough consideration. Exception may perhaps be taken to the relative amounts of space accorded some of the medicaments described. For example, nine pages are devoted to a detailed description of so-called antisyphilitic mercurials while only three pages are devoted to bismuth which has practically supplanted

ed them in the treatment of syphilis. Tryparsamide receives consideration of only half a page. Lapses of the preceding nature are, however, relatively few. The book on the whole is well done. It is excellently printed, and is subdivided in such a manner that it makes a very fit source of study for the medical student and reference for the physician.

Leçons de Physiologie Médico Chirurgicalle Leon Binet 244 pp Paris Masson et Cie 40 fr

There are presented in this protocol sixteen conferences on the physiologic aspects of various medical and surgical problems of importance. Included in the wide diversity of discussed subjects is a study of induced pneumothorax in tuberculosis, the treatment of acute hemorrhagic pancreatitis and experimental acute nephritis, the pathogenesis and treatment of peptic ulcer, intestinal obstruction, functional exploration of the spleen, the colon bacillus, the arterial atheromata and the agents employed in the treatment of rickets. Although primarily of physiologic importance, the contributions of Professor Binet and his collaborators will be read with profit by the internist and surgeon as well.

Aids to Ophthalmology N. Bishop Harman Eighth Edition 242 pp Baltimore William Wood & Company \$1.25

This work constitutes an excellent pocket manual for the student of medicine, for whom a series of similar aids have been written by British authors.

Rare diseases are omitted, and emphasis is given to the more common eye diseases and to their relation to general medicine. The subject matter is well presented, and it carries 203 helpful illustrations. While *Aids to Ophthalmology* cannot be considered complete enough to serve as a book of reference, it does serve a useful purpose as a supplement to case teaching for the student who is first undertaking clinical work.

Diet Control A system of eleven hundred diets for the prescription of diabetic, anti-obesity and measured diets in general. George E. Anderson and Paul C. Eschweiler New York City Gallo & Ackerman, Inc.

This work is not a book but consists of a descriptive pamphlet of the principles of treatment for the physician, and a dozen detachable pamphlets of diet prescription for patients. The purpose of the authors in applying diet control in this way is to facilitate yet to keep accurate the selection of foods by patients. In each of the pamphlets of diet prescriptions there is an explanatory introduction of the treatment, and this is followed by lists of measured but not weighed foods that may be selected by the patients at the three meals. The work should be found useful for practitioners who frequently prescribe diets.

The New England Journal of Medicine

VOLUME 213

OCTOBER 24, 1935

NUMBER 17

PSYCHOPATHY AND THE GENERAL PRACTITIONER*

BY HORACE K. RICHARDSON, M.D.†

TO the practitioner of medicine, cases of mental illness and emotional disorder occurring among those who come to him for assistance constitute one of the gravest and most troublesome problems with which he is obliged to deal because of their protean aspects and complex phenomena. These cases will naturally fall into two large nosological groups, namely, the psychotic, or those cases suffering with the frank mental diseases, and those that come under the general classification of the psychoneurotic.

About the first class, the psychotic, I shall have but little to say, because ordinarily they will present few difficulties in differential diagnosis, and the solution of them, from the viewpoint of the practitioner, is generally immediate commitment or hospitalization. Because of the gross interference with the usual mental habits, the very obvious changes in the common beliefs, personality expressions and mannerisms of the patient, the physician will rarely have much difficulty in convincing the members of his family that a serious condition is present. The cooperation of the family with the plan to hospitalize the patient usually will be easily obtained, and there should be little delay in its execution.

It is the latter group, made up of the various psychoneuroses, the baffling borderline cases and the innumerable emotional states and undefined, subtle maladaptations which disturb the lives and invade the homes of so many individuals, that will give the practitioner his greatest concern, tax his patience almost to the point of exasperation, challenge his resourcefulness to its maximum, and frequently require a high degree of sophistication and intuition for their solution. It is to this class that we shall devote our attention in this discussion.

Man's early mental life consisted almost entirely of efforts directed toward an understanding of the elemental forces of nature, and their effects upon his physical existence. As his intelligence increased and he reached the stage in his development where he found it no longer necessary to devote the major part of his time to the pursuit of life-saving activities, he must

have become aware of the fact that an inner being had been developing within himself, and for the first time he began to visualize an inner, more permanent, identifying quality, apart from his outside world. He began to experience the amazements of consciousness. We can very well imagine that in the course of time, he began to have ruminations relative to the various attributes of the conscious state, and to ponder and theorize upon its nature.

As the severity of life conditions softened, and man's interests broadened, he turned to the exploration of the neighboring country, and thus made contacts with other groups. This led to commerce. These activities brought riches, which in turn brought leisure, time in which the struggle for bare existence was temporarily suspended or anticipated, and in which opportunities for contemplation and introspection were presented.

We can imagine that the mystery of his personality occupied the mind of man to a greater and greater degree, and finally he began to discuss it with his fellows. Attempts at interpretation and explanation must have been largely colored by mysticism and the supernatural, but as experience broadened, his concepts became orientated and crystallized, and finally he developed the discipline of associative thought. The individual then began to be able to profit by his previous experience. Later the method of thinking called "Science" began to operate, and to be applied to various categories and conditions, of course without success of solution, because his problems were not yet susceptible of definite formulation. Centuries later, philosophy developed and finally became resolved into its fundamental elements and out of these formulations the Art of Medicine originated.

As late as 470 B.C., when Sparta and Athens had joined forces and definitely turned back the advance of Oriental conquest and culture, and were able to give themselves up to the peaceful pursuit of philosophical speculation, their philosophy was confined almost exclusively to the physical aspects of life.

It was at about this point in the development of the world of ideas, that Hippocrates flourished, and it was at this time that he gave to Medicine its first indelible scientific impression. From out of the welter of medical superstition,

Annual Alumni Address Tufts College Medical School, May 14, 1935.

Richardson, Horace K.—Assistant Medical Director, The Austin Riggs Foundation, Rockbridge, Mass. For record and address of author see "This Week's Issue" page 822.

theoretical assumptions, and the numerous philosophies concurrent with his time, he sifted out what he thought to be the factual material, and established the first synthesis of rational knowledge relative to the diseases and disorders of mankind

Later Socrates, 469-389 B C, turned his investigative searchlight within questioning, doubting, analyzing, not only the physical life of man, but especially his inner mental life, and as a result of his labors, gave to the world the compelling formulation, "Gnothe Seauton," "Know Thyself" This was a new and revolutionary attitude It came to fruition during the Athenian period in the form of an encyclopedic interest in about every quality of man, including his psychic self and his dream life

Plato anticipated Freud's interpretation of man's unconscious, the mechanism of repression, and of his dream life, as illustrated by the following quotation from his work "Certain of the unnecessary pleasures and instincts are deemed to be unlawful, every man appears to have them, but in some persons they are subjected to the control of law and reason, and the better desires prevailing over them they are either wholly suppressed, or reduced in number, while in other persons these desires are stronger and more abundant I mean particularly those desires which are awake when the reasoning and taming and ruling power of the personality is asleep, the wild beast in our nature, gorged with meat and drink, starts up and walks about naked, and surfeits at his will, and there is no conceivable folly or crime, however shameless or unnatural—not excepting incest and parricide—of which such a nature may not be guilty But when a man's pulse

is healthy and temperate, and he goes to sleep cool and rational having indulged his appetites neither too much nor too little, but just enough to lay them to sleep he is then least likely to be the sport of fanciful and lawless visions In all of us even in good men, there is such a latent wild beast nature which peeps out in sleep"

After the fall of Athens, 404 B C there was a period during which Oriental fatalism and determinism flourished During the period from 336-270 B C, the philosophy of resignation of the Stoics and the efforts of the Epicureans to nullify the painful in the psychic and physical lives of man dominated the philosophic trends of thought

Later came the Romans, the first of the pragmatists, and then the Christian ideal founded wholly upon philosophical faith, in contradistinction to the wavering flame of scientific method, of searching for facts that had just been ignited by the Greeks

By the year 1096 A.D., the Crusades had begun, and the monastic attitude dominated the world of ideas During the eleventh, twelfth

and thirteenth centuries, the attitudes and interests of the majority of the peoples of the civilized world gradually, but completely, changed from those of the preceding centuries With a fine ascetic disregard for the world, and the philosophies of materialism and the flesh, they were searching for solutions to the problems of the spirit, and in the salvation of their souls The scientific method and the art of medicine went into a long period of scholastic lethargy

The point I wish to make is, that for centuries, man had moved in and out of long periods of contemplation of either his physical self, his mental life or his spiritual awareness Never had there been any broad propelling attempt to bring these three intrinsic fundamentals of man together, and to visualize him as a synthetic, biological entity Each characteristic was isolated from the others in thought-proof compartments, and man, for the most part, looked upon each as having a separate existence and an independent function There had been no concept of an integrated, interdependent relationship, or of a "total personality"

Spinoza, in the seventeenth century, made a definite attempt to destroy the distinction between an independent body and an independent mind and to eliminate this attitude of biological fragmentation He attempted to create a "body-mind" relationship The attitudes of the eighteenth and nineteenth centuries, slowly added impetus to the growing belief in the unity of man, but it was not until the early years of the twentieth century, when Sherrington published his monumental and revolutionary work, "The Integrative Action of the Nervous System," and Adolf Meyer established his epoch-making concept of psychobiological integration of the personality, that any real advance was made toward an understanding of the basic fundamentals of the personality or of the dynamics of mental disorders Sherrington's efforts directed toward synthetic structuralization of nervous function, and the dynamic-genetic concepts of Meyer, together, materially clarified the situation, and for the first time in medical thought there was a definite discipline in our ideas of psychopathy and a rational basis for an understanding of their mechanics The implications of integration gave a new philosophical insight into the origin and meaning of mental disorders We had been looking at them too long from a pragmatic attitude alone

For years man had thought of disease and disorder as occurring either within his mind or within his body The interrelation between the mental and the physical had not been appreciated, and not until Sherrington and Meyer published their works, was there any real suggestion of psychosomatic correlation We now recognize and appreciate the fact that it is this

integrative function of the nervous system that makes adaptation to life possible. Interferences with this integration make maladaptations to life equally possible, and it is through and by this integrated whole that they express themselves. It is likewise responsible for the mystery and the baffling incongruity of the symptomatology seen in many of the neuroses.

From the above, we conclude that there is in the central nervous system a centralization of the function of living, and of the life forces, due to a harmonious coördinated, regulated co-operation of all its parts. At this point a brief review of our knowledge of these parts may assist in a further understanding of the discussion of certain clinical aspects of psychopathy which is to follow.

For convenience, we separate the nervous system into three major divisions, namely the brain, the spinal cord and the nerves. The latter are divided into the sensory neurons, the motor neurons, and the sympathetics. The function of the sensory neurons is to bring to the awareness of the individual, in the form of sensations, perceptions of his environment, as well as information relative to the state of his inner self. It is only through the sensory mechanism that man knows what is going on about him, or that he becomes aware of changes occurring within his own physical and psychic self.

The motor neurons, through the musculature, permit expression of man's will and desire in the form of conduct, behavior or action. They also serve various glandular structures. The sympathetics form the connecting link between the inner organic life of the individual and the higher, psychic functions of the central nervous system. They are closely related to the fundamental, archaic instinctive life of the personality, and represent an inheritance from the time when the early animal types had no thinking machine with which to adapt themselves to the circumstances of their environment.

The function of the spinal cord is similar to that of a great cable which provides specific pathways for the transmission of the sensory neurons coming in from the various end-organs, and going up to the brain, and for paths for the motor neurons coming down from the brain, and going out to the muscles, organs and glands. The sympathetics are also carried up and down within the cord, and within it, also are various reflex arcs which make for certain automatic acts outside of consciousness.

The functions of the brain are as follows: first the reception and transmission of nerve impulses, as in the reception of sensory messages, and the formation of perceptions which are, in turn, transmitted to the motor centers as thinking and to the hypothalamus as emotion or feeling and secondly the storing up of these

messages in consciousness. No one of these three components is lost. Every sensation, every thought or idea, every emotion or feeling is stored up permanently in consciousness in the form of individual experience, and they are grouped together according to the law of association.

We are in the habit of speaking of various levels of nervous function, as for instance the psychological level, which is represented by thinking and the psychic life, and located in the cortex, and the vegetative, or physiological level centered in the medulla, and represented by the more automatic functions of circulation, respiration and digestion. While these vegetative centres are located within the medulla, they are connected with the higher functions by neurons, and are being modified by psychic influences which flow to them in a constant stream from the cortical centres. In other words, between the higher and lower structural centres, and the various functional levels, associative neurons join all the numerous activities into a harmonious, well-coördinated, synthetic interrelationship, which functions for the good of the organism as a whole.

Now through all these structures, from the cortex down to the medulla, and through all the functional levels from the psychological down to the physiological, there are two great antagonistic currents constantly playing, the one tending to initiate maintain and express action, the other tending to stop retard and repress action. Of their fundamental nature, we are in ignorance, they may be electrical. We know them only by their works. Without them, there would be no controlled life, with them, an efficient expression of the flow of energy within the nervous system is made possible. These two opposing influences are excitation and inhibition. In the vegetative system, we witness their effect in the excitant action of the sympathetics and the inhibitory action of the vagus on the heart rate. In the psychic sphere, we see the excitation of the instincts meeting the inhibitory forces of conscience.

It is the antagonistic character of these two principles that is responsible for the production of psychic conflict in man, and furnishes the basis for the origin and development of his maladaptations. An inharmonious relationship between the two lower levels of the personality as represented by the habit patterns and the instinctive emotions, and the two higher levels, as represented by intelligence and conscience always furnishes the causative background of the psychoneuroses. When this conflict is expressed through the effect of the emotions upon the sympathetic nervous system and the hypothalamus, the symptomatology becomes dominated by functional disorders, with the produc-

tion of unusual sensory disturbances in the organs, glands, joints, muscles, circulation, etc. When it is expressed through the cortical structures and functions, it takes the form of unusual psychic expressions as in obsessional thoughts and ruminations, phobias, compulsions, impulsions, fixed ideas and anxiety states. It is only to the former class that we shall devote our attention in this paper. We shall not discuss those cases which express themselves through the latter routes.

In view of all this, we must no longer think in terms of diseased organs within a man, but remember that we are treating a person as a whole in time-contact with the world about him. We are not treating an individual isolated from his environment or from his cultural, moral, economic and social past, but we are treating a person surrounded by many conditions and factors, and immersed in many influences, endogenous as well as exogenous, that tend to modify and determine the character of the total objective picture. We cannot separate an organically ill man from his habit patterns, his unconscious instinctive tendencies or his repressed conflicts, and therefore, when we attempt to treat a person with a diseased or disordered heart, for example, we must approach both the heart and the man together as a total situation, and in view of the effects that the above life factors have upon it. Again it is the integrative, dynamic, genetic aspects of the nervous system as a whole that make this attitude necessary and valuable. As Doctor Frederick Tilney has said: "In the main, we have made disease our chief interest. As a matter of fact, life is the principal theme, to which disease is but a corollary. The purely pragmatic attitude toward medicine is not without its defects. It fails to encourage an approach to the salient problems concerning the significance of life, it omits, as theoretical, the considerations of development and adaptation. Although it lends facility to professional administration it does not establish the philosophical attitude upon which the advance as well as the practice of medicine ultimately depend."

It has been estimated that between fifty and seventy-five per cent of all cases of illness coming before the physician for assistance fall into the class of functional disorders of the nervous system. I have been informed by reliable persons that last year one of our large surgical clinics of the higher type turned back to referring physicians, for psychiatric investigation, fifty-six per cent of all cases sent there for abdominal operations. Investigation had failed to disclose the necessity for the surgical interference for which the cases had been originally referred. In our own work at the Riggs Foundation, each year we see a large number

of cases which have gone through the gamut of surgical exploration, radical removal of organs, or internal investigations and treatment, with no subsequent amelioration of the sensory symptoms for which the procedures were instituted.

We receive many cases which have been diagnosed as organic, which prove to be, upon further study, hysterical conversions, or substitute reactions for repressed emotional states, and which are cured by the application of the proper psychotherapeutic methods. On the contrary, we also receive cases which have been diagnosed as hysterical, which prove to be organic. Many cases of postepidemic encephalitis fall into this class.

When we begin to investigate illness in the light of the above principles, we frequently discover startling correlations and amazing incongruities in human behavior, especially in those cases where adequate histories and skillful examinations are utilized as the basis for our interpretations. If I can leave but one valuable thought with you as the result of this hour, I hope it may be that you have been impressed with the necessity for making accurate and complete histories, and skillful and painstaking examinations time consuming as they are. Carelessness in these two factors is responsible for many errors in diagnosis.

You are going to come in contact with many patients who come to you in your office, in clinic or in hospital, complaining of various pains, discomforts and disorders in different parts of their bodies, where complete examinations and accurate laboratory test, disclose no organic pathology whatever. Many times you will meet confusion, doubt and despair in attempting to arrive at a proper evaluation of the situation at hand. Frequently, it will take every particle of honesty you possess to treat these cases. Even after a consideration of all the facts at your disposal, often, diagnosis will be impossible. If you have learned to include in your routine examinations and histories, not only an account of the frank physical symptomatology, but in addition, facts relative to the life situations and environmental influences in which the person lives, something about his usual emotional reactions, his desires, hopes and ambitions, his discontents, his defeats and his inner habit patterns of reaction to responsibility, disappointment, frustration and failure, frequently, you will be surprised to discover causes for what otherwise would seem bizarre and inconsistent physical symptoms. You will bring about occasionally, what seem to be miraculous cures if you will but include in your histories, and give full value to the facts or psychic insult, as well as of physical trauma, to psychopathology as well as to physical pathology.

Just what should be our attitude and procedure, for example, in the following case that has lately come to my attention? Here is a man of forty years. He possesses an unusual degree of intelligence, he is well educated and has high cultural qualities. Apparently there is no reason why he should not be as happy as most of us. He has a nice family, a charming wife and assured income, and has no special discontent with his social situation. Several months ago he began to suffer with what he described as "spells", in which he suddenly finds his heart pounding, his breath coming in gasps, his pulse rate rapidly mounting to 120 per minute and his body breaking out in drenching perspiration. At the same time he is consumed with what he expresses, as a "silly and unfounded paralyzing fear of impending disaster", and for days following the attacks, he is confined to his home completely incapacitated because of the actual physical discomforts associated with respiration and circulation, and because of a fear of a return of the so-called "spells". Repeated clinical examinations by reputable internists have failed to disclose any pathological conditions of any kind. Now what shall be our attitude? Shall we give him a prescription for a placebo of attractive appearance and fine flavor as a substitute for a cocktail before meals, or shall we tell him that there is nothing the matter with him, and that his attacks are "all imagination" and that he "must snap out of it", or "forget it"? Or shall we suggest that he take a long journey, or a sea trip hoping that some kind genie will solve his problem for him before he returns? Or shall we take an intelligent, humane, scientific attitude toward this unhappy man and search for causes in fields other than in the purely organic? Not in the "body" alone, but in the "body mind" machine, not simply in the physical realm, but in the psychic as well.

An investigation into the facts at our command in this case discloses some interesting data. We noted that his attacks began some months ago. In looking into the experiences of this man just prior to the onset of the attacks, we find that he had had no physical illness in fact he reported that he had been feeling unusually well at the time. Nothing of any importance had happened to interfere with his domestic or social relationships. He had done nothing about which to be especially ashamed or sorry. There had been no reduction in income. On the contrary, he had just been promoted in the organization in which he worked. In his own mind, he had simply been taken suddenly ill with a physical disease, and no one had been able to discover its cause.

In going farther into the facts of his commercial life, however, we discover that his attacks first came on within one week after he had received this promotion. Could this have had

anything to do with the onset? He thought not. "How could such a happy event?", he said, "have anything to do with the production of the symptom picture" which we have described?

This man had served for several years as an efficient assistant to one of the department chiefs. He was well liked, accommodating, conscientious, cooperative and willing, and he possessed a wide fund of knowledge about the mechanics of the department in which he had worked. His chief was a domineering, efficient person, however, who made a practice of planning and directing most of the details himself. He was unable to delegate authority, or to take his assistant into his full confidence and therefore this able assistant had been trained in everything having to do with his work, except that of planning, exercising authority and assuming responsibility. When his chief died suddenly, and he found himself promoted because of seniority, to his position where he was obliged to assume all the responsibility for planning and directing, his personality suddenly demonstrated his inadequacy to carry this type of load. Unconscious emotional conflicts developed within himself because of the threat to his ego implied by the assumption of the responsibilities of his new position. Consciously man cannot admit failure easily, and this man, therefore, repressed his fear of failure from his awareness. Unconscious processes then took up the problem and acted as though they had a will of their own in that they seemed to have the power to get the individual out of the situation and at the same time save his personal pride. In this man, the emotional component of the complex, through its influences upon the sympathetics, set up a disturbance in the automatic functions on the physiological level, and produced the somatic symptom picture as above. As a result of what appeared to him to be entirely a physical illness, he was removed from the painful situation and he left with no impairment of his self respect and with no conscious realization of his inadequacy.

Now is this the whole story? No. It is not quite so simple as that. The promotion to the position of responsibility was simply the precipitating cause of the disorder. It simply reactivated and set in motion certain factors that were already in the personality make-up of the man at the time. The real source of his trouble lay deep within his personality structure in the form of habit patterns which were formed as a result of the environmental pressures, disciplines, admonitions and criticisms from those whom he loved or feared, before he reached the age of discrimination or judgment. Simply by the flight and pressure of time, they had been automatically pushed away into the unawareness, with the immature, nonlogical emotional values formed in childhood still attached to them. Other pertinent facts included the influences of a father who had always criticized the

tion of unusual sensory disturbances in the organs, glands, joints, muscles, circulation, etc. When it is expressed through the cortical structures and functions, it takes the form of unusual psychic expressions as in obsessional thoughts and ruminations, phobias, compulsions, impulsions, fixed ideas and anxiety states. It is only to the former class that we shall devote our attention in this paper. We shall not discuss those cases which express themselves through the latter routes.

In view of all this, we must no longer think in terms of diseased organs within a man, but remember that we are treating a person as a whole in time-contact with the world about him. We are not treating an individual isolated from his environment or from his cultural, moral, economic and social past, but we are treating a person surrounded by many conditions and factors, and immersed in many influences, endogenous as well as exogenous, that tend to modify and determine the character of the total objective picture. We cannot separate an organically ill man from his habit patterns, his unconscious instinctive tendencies or his repressed conflicts, and therefore, when we attempt to treat a person with a diseased or disordered heart, for example, we must approach both the heart and the man together as a total situation, and in view of the effects that the above life factors have upon it. Again it is the integrative, dynamic, genetic aspects of the nervous system as a whole that make this attitude necessary and valuable. As Doctor Frederick Tilney has said: "In the main, we have made disease our chief interest. As a matter of fact, life is the principal theme, to which disease is but a corollary. The purely pragmatic attitude toward medicine is not without its defects. It fails to encourage an approach to the salient problems concerning the significance of life, it omits, as theoretical, the considerations of development and adaptation. Although it lends facility to professional administration, it does not establish the philosophical attitude upon which the advance as well as the practice of medicine ultimately depend."
